The GNU Modula-2 Compiler

Release 13.0.1 (experimental 20220101)

Gaius Mulley

Nov 07, 2022

CONTENTS

CHAPTER

ONE

WHAT IS GNU MODULA-2

GNU Modula-2 is a front end for the GNU Compiler Collection (GCC). The GNU Modula-2 compiler is compliant with the PIM2, PIM3, PIM4 and ISO dialects. Also implemented are a complete set of free ISO libraries and PIM libraries.

The four Modula-2 dialects supported are defined in the following references:

PIM2: 'Programming in Modula-2', 2nd Edition, Springer Verlag, 1982, 1983 by Niklaus Wirth (PIM2).

PIM3: 'Programming in Modula-2', 3rd Corrected Edition, Springer Verlag, 1985 (PIM3).

PIM4: 'Programming in Modula-2', 4th Edition, Springer Verlag, 1988 (PIM4).

ISO: the ISO Modula-2 language as defined in 'ISO/IEC Information technology - programming languages - part 1: Modula-2 Language, ISO/IEC 10514-1 (1996)'

CHAPTER

TWO

WHY USE GNU MODULA-2

There are a number of advantages of using GNU Modula-2 rather than translate an existing project into another language.

The first advantage is of maintainability of the original sources and the ability to debug the original project source code using a combination of gm2 and gdb.

The second advantage is that gcc runs on many processors and platforms. gm2 builds and runs on powerpc64le, amd64, i386, aarch64 to name but a few processors.

The compiler provides semantic analysis and runtime checking (full ISO Modula-2 checking is implemented) and there is a plugin which can, under certain conditions, detect runtime errors at compile time.

gm2 can produce swig interface headers to allow access from Python and other scripting languages. The compiler supports PIM2, PIM3, PIM4 and ISO dialects of Modula-2, work is underway to implement M2R10. Many of the GCC builtins are available and access to assembly programming is achieved using the same syntax as that used by GCC.

CHAPTER

THREE

RELEASE MAP

GNU Modula-2 is now part of GCC and therefore will adopt the GCC release schedule with a git branches matching the various GCC release numbers. It is intended that GNU Modula-2 implement more of the GCC builtins (vararg access) and GCC features.

There is an intention to implement the M2R10 dialect of Modula-2 and any of the language changes. If you wish to see something different please email gm2@nongnu.org with your ideas.

CHAPTER

FOUR

NEWS

gm2 release numbers
: are now superceded by gcc branch numbers as gm2 is tracking the gcc release model.

accuracy of error messages
: has been improved and offending subexpressions are now highlighted.

new type checker
: has been implemented which will check all data types, including recursive procedure parameter types.

libraries
: the gm2 driver program has been enhanced to allow third party libraries to be installed alongside gm2 libraries. For example if the user specifies library `foo` using `-flibs=foo` the driver will check the standard GCC install directory for a subdirectory `foo`.

libpth
: has been removed from gm2 and the coroutines are now implemented using the gcc portable threading library.

libulm
: the Ulm libraries have been removed from the gm2 tree as they were not GPL3.

Talk given at The GNU Tools Cauldron 2018
: here is a talk on GNU Modula-2 given at The GNU Tools Cauldron, Manchester on 8th September 2018. The title is, 'GNU Modula-2 update, catching semantic errors post code optimisation and improved debugging' [slides and video].

gm2 1.8.2
: was released on Aug 30th 2018. gm2-1.8.2 grafts onto gcc-8.2.0 and contains integer overflow detection for addition, subtraction, negation and multiplication. It also detects and traps when a floating point nan occurs. This is the first release with the new semantic checking plugin which checks whether any exception will occur post optimization (see -fsoft-check-all). The compiler also works well with the automake tools.

gm2 1.2.0
: was released on May 11th 2017. gm2-1.2.0 grafts onto gcc-5.2.0 and supports much better line number accuracy in debugging output. Source to code relationship can be further improved by the new option -fm2-g. -fm2-whole-program also provides whole program optimization.

Talk given at The GNU Tools Cauldron 2016
: here is a talk on GNU Modula-2 given at The GNU Tools Cauldron, Hebden Bridge on 9th September 2016. The title is, 'GNU Modula-2 status, whole program optimisation and language interoperability' [slides and video].

gm2 1.1.6
: was released on February 22nd 2016. gm2-1.1.6 grafts onto gcc-4.7.4.

gm2 1.1.5
: was released on September 3 2015, passes all regression tests and has many bug fixes applied. Arrays and Records can be assigned to and from WORD, LOC, BYTE providing sizes permit. Also a small number of fixes to the library module MemStream.mod. Fixed a number of bugs shown by valgrind.

gm2 1.1.3
: was released on April 15 2015. gm2-1.1.3 passes all regression tests on Debian Wheezy (x86_64) and (i686). Also passes all regression tests under Debian Jessie (x86_64). It also builds on armv7l Ubuntu Trusty Tahr.

gm2 1.1.1
: was released on January 26 2015. gm2-1.1.1 passes all regression tests on Debian Wheezy (x86_64) and (i686). Also passes all regression tests under Debian Jessie (x86_64).

gm2 1.1.0
: was released on January 02 2015. gm2-1.1.0 passes all regression tests on Debian Wheezy (x86_64) and (i686).

gm2 1.0.9
: Beta was released on September 23 2014, all regressions passed on x86_64 Debian Wheezy.

gm2 1.0.4
: was released on September 30 2011. This is a bug fix release.

gm2 1.0
: was released on December 11 2010.

CHAPTER

FIVE

HOW TO GET SOURCE CODE USING GIT

GNU Modula-2 is in the process of migrating into the GCC git tree. The development branch is available via git:

```
$ git clone git://gcc.gnu.org/git/gcc.git gcc-git-devel-modula2
$ cd gcc-git-devel-modula2
$ git checkout devel/modula-2
$ cd ..
```

GNU Modula-2 is in the process of migrating into the GCC git tree. See development section in this GM2 documentation for git details and See gcc:downloading-the-source in the GCC documentation.

CHAPTER

SIX

GNU MODULA-2 FEATURES

- the compiler currently complies with Programming in Modula-2 Edition 2, 3, 4 and ISO Modula-2. Users can switch on specific language features by using: `-fpim`, `-fpim2`, `-fpim3`, `-fpim4` or `-fiso`.
- the option `-fswig` will automatically create a swig interface file which corresponds to the definition module of the file being compiled.
- exception handling is compatible with C++ and swig. Modula-2 code can be used with C or C++ code.
- Python can call GNU Modula-2 modules via swig.
- shared libraries can be built.
- fixed sized types are now available from `SYSTEM`.
- support for dynamic `ARRAY` s has been added into `gdb`.
- variables can be declared at addresses.
- much better dwarf-2 debugging support and when used with `gdb` the programmer can display `RECORD` s, `ARRAY` s, `SET` s, subranges and constant char literals in Modula-2 syntax.
- supports sets of any ordinal size (memory permitting).
- easy interface to C, and varargs can be passed to C routines.
- many Logitech libraries have been implemented and can be accessed via: `-flibs=m2log,m2pim,m2iso`.
- coroutines have been implemented in the PIM style and these are accessible from SYSTEM. A number of supporting libraries (executive and file descriptor mapping to interrupt vector libraries are available through the `-flibs=m2iso,m2pim` switch).
- can be built as a cross compiler (for embedded microprocessors such as the AVR and the ARM).

CHAPTER

SEVEN

DOCUMENTATION

The GNU Modula-2 documentation is available on line at the gm2 homepage or in the pdf, info, html file format.

CHAPTER

EIGHT

REGRESSION TESTS FOR GM2 IN THE REPOSITORY

The regression testsuite can be run from the gcc build directory:

```
$ cd build-gcc
$ make check -j 24
```

which runs the complete testsuite for all compilers using 24 parallel invocations of the compiler. Individual language testsuites can be run by specifying the language, for example the Modula-2 testsuite can be run using:

```
$ cd build-gcc
$ make check-m2 -j 24
```

Finally the results of the testsuite can be emailed to the gcc-testresults list using the script:

```
$ gccsrcdir/contrib/test_summary
```

CHAPTER

NINE

LIMITATIONS

Logitech compatibility library is incomplete. The principle modules for this platform exist however for a comprehensive list of completed modules please check the documentation gm2.html.

CHAPTER

TEN

OBJECTIVES

- The intention of GNU Modula-2 is to provide a production Modula-2 front end to GCC.
- It should support all Niklaus Wirth PIM Dialects [234] and also ISO Modula-2 including a reimplementation of all the ISO modules.
- There should be an easy interface to C.
- Exploit the features of GCC.
- Listen to the requests of the users.

CHAPTER

ELEVEN

FAQ

11.1 Why use the C++ exception mechanism in GCC, rather than a bespoke Modula-2 mechanism?

The C++ mechanism is tried and tested, it also provides GNU Modula-2 with the ability to link with C++ modules and via swig it can raise Python exceptions.

CHAPTER

TWELVE

COMMUNITY

You can subscribe to the GNU Modula-2 mailing by sending an email to: gm2-subscribe@nongnu.org or by http://lists.nongnu.org/mailman/listinfo/gm2. The mailing list contents can be viewed http://lists.gnu.org/archive/html/gm2.

CHAPTER

THIRTEEN

OTHER LANGUAGES FOR GCC

These exist and can be found on the frontends web page on the gcc web site.

CHAPTER

FOURTEEN

PAPERS AND TALKS

A paper was presented at the GCC 2006 conference on the state of GNU Modula-2.

A lightening talk has been given at the GCC 2010 conference titled “Exploiting front end knowledge to effortlessly create Python modules” and the slides are available.

CHAPTER

FIFTEEN

USING GNU MODULA-2

15.1 Example compile and link

@c man begin SYNOPSIS gm2 gm2 [@option{-c}|@option{-S}] [@option{-g}] [@option{-pg}]

[@option{-O}@var{level}] [@option{-W}@var{warn}…] [@option{-I}@var{dir}…] [@option{-L}@var{dir}…] [@option{-f}@var{option}…] [@option{-m}@var{machine-option}…] [@option{-o} @var{outfile}] [@@@var{file}] @var{infile}…

Only the most useful options are listed here; see below for the remainder. @c man end @c man begin SEEALSO gpl(7), gfdl(7), fsf-funding(7), gcc(1) and the Info entries for @file{gm2} and @file{gcc}. @c man end The **gm2** command is the GNU compiler for the Modula-2 language and supports many of the same options as **gcc**. See Option Summary. This manual only documents the options specific to **gm2**.

This section describes how to compile and link a simple hello world program. It provides a few examples of using the different options mentioned in see Compiler options. Assuming that you have a file called `hello.mod` in your current directory which contains:

```
MODULE hello ;

FROM StrIO IMPORT WriteString, WriteLn ;

BEGIN
   WriteString('hello world') ; WriteLn
END hello.
```

You can compile and link it by: `gm2 -g hello.mod`. The result will be an `a.out` file created in your directory.

You can split this command into two steps if you prefer. The compile step can be achieved by: `gm2 -g -c -fscaffold-main hello.mod` and the link via: `gm2 -g hello.o`.

To see all the compile actions taken by `gm2` users can also add the `-v` flag at the command line, for example:

```
gm2 -v -g -I. hello.mod
```

This displays the subprocesses initiated by `gm2` which can be useful when trouble shooting.

15.2 Compiler options

This section describes the compiler options specific to GNU Modula-2 for generic flags details See GCC Command Options.

For any given input file, the file name suffix determines what kind of compilation is done. The following kinds of input file names are supported:

***file*.mod**
: Modula-2 implementation or program source files. See the `-fmod=` option if you wish to compile a project which uses a different source file extension.

***file*.def**
: Modula-2 definition module source files. Definition modules are not compiled separately, in GNU Modula-2 definition modules are parsed as required when program or implementation modules are compiled. See the `-fdef=` option if you wish to compile a project which uses a different source file extension.

  You can specify more than one input file on the **gm2** command line,

-g
: create debugging information so that debuggers such as `gdb` can inspect and control executables.

-I
: used to specify the search path for definition and implementation modules. An example is: `gm2 -g -c -I.:../../libs foo.mod`. If this option is not specified then the default path is added which consists of the current directory followed by the appropriate language dialect library directories.

-fdebug-builtins
: call a real function, rather than the builtin equivalent. This can be useful for debugging parameter values to a builtin function as it allows users to single step code into a real function.

-fdump-system-exports
: display all inbuilt system items. This is an internal command line option.

-fswig
: generate a swig interface file.

-fshared
: generate a shared library from the module.

-fruntime-modules=
: specify, using a comma separated list, the runtime modules and their order. These modules will initialized first before any other modules in the application dependency. By default the runtime modules list is set to `Storage,SYSTEM,M2RTS,RTExceptions,IOLink`. Note that these modules will only be linked into your executable if they are required. So adding a long list of dependant modules will not effect the size of the executable it merely states the initialization order should they be required.

-fnil
: generate code to detect accessing data through a `NIL` value pointer.

-fno-nil
do not generate code to detect accessing data through a `NIL` value pointer.

-fwholediv
generate code to detect whole number division by zero or modulus by zero.

-fno-wholediv
do not generate code to detect whole number division by zero or modulus by zero.

-findex
generate code to check whether array index values are out of bounds.

-fno-index
do not generate code to check whether array index values are out of bounds.

-frange
generate code to check the assignment range, return value range set range and constructor range.

-fno-range
do not generate code to check the assignment range, return value range set range and constructor range.

-freturn
generate code to check that functions always exit with a `RETURN` and do not fall out at the end.

-fcase
turns on compile time checking to check whether a `CASE` statement requires an `ELSE` clause when on was not specified.

-fsoft-check-all
turns on all runtime checks. This is the same as invoking GNU Modula-2 using the command options `-fnil -frange -findex`

`-fwholediv -fcase -freturn`.

-fauto-init
turns on auto initialization of pointers to NIL. Whenever a block is created all pointers declarated within this scope will have their addresses assigned to NIL.

-fno-exceptions
turns off all generation of exception handling code and no references are made to the runtime exception libraries.

-v
display all calls to subsidiary programs, such as the C preprocessor, the GNU Modula-2 linker and compiler.

-fm2-statistics
generates quadruple information: number of quadruples generated, number of quadruples remaining after optimisation and number of source lines compiled.

-fm2-whole-program
compile all implementation modules and program module at once. Notice that you need

to take care if you are compiling different dialect modules (particularly with the negative operands to modulus). But this option, when coupled together with `-O3`, can deliver huge performance improvements.

`-fm2-g`
improve the debugging experience for new programmers at the expense of generating `nop` instructions if necessary to ensure single stepping precision over all code related keywords. An example of this is in termination of a list of nested `IF` statements where multiple `END` keywords are mapped onto a sequence of `nop` instructions.

`-fm2-lower-case`
render keywords in error messages using lower case.

`fno-pthread`
do not automatically link against the pthread library. This option is likely useful if gm2 is configured as a cross compiler targetting embedded systems. By default GNU Modula-2 uses the GCC pthread libraries to implement coroutines (see the SYSTEM implementation module).

`-fuse-list=`*`filename`*
if `-fscaffold-static` is enabled then use the file `filename` for the initialization order of modules. Whereas if `-fscaffold-dynamic` is enabled then use this file to force linking of all module ctors. This option cannot be used if `-fgen-module-list=` is enabled.

`-fgen-module-list=`*`filename`*
attempt to find all modules when linking and generate a module list. If the `filename` is `-` then the contents are not written and only used to force the linking of all module ctors. This option cannot be used if `-fuse-list=` is enabled.

`-fscaffold-static`
the option ensures that `gm2` will generate a static scaffold within the program module. The static scaffold is useful for debugging and single stepping the initialization blocks of implementation modules.

`-fscaffold-dynamic`
the option ensures that `gm2` will generate a dynamic scaffold infastructure when compiling implementation and program modules. By default this option is on. Use `-fno-scaffold-dynamic` to turn it off or select `-fno-scaffold-dynamic`.

`-fcpp`
preprocess the source with `cpp -lang-asm -traditional-cpp` For further details about these options See Invocation. If `-fcpp` is supplied then all definition modules and implementation modules which are parsed will be preprocessed by `cpp`.

`-fiso`
turn on ISO standard features. Currently this enables the ISO `SYSTEM` module and alters the default library search path so that the ISO libraries are searched before the PIM libraries. It also effects the behaviour of `DIV` and `MOD` operators. See GNU Modula-2 supported dialects.

`-fpim`
turn on PIM standard features. Currently this enables the PIM `SYSTEM` module and determines which identifiers are pervasive (declared in the base module). If no other `-fpim[234]` switch

is used then division and modulus operators behave as defined in PIM4. See GNU Modula-2 supported dialects.

-fpim2
turn on PIM-2 standard features. Currently this removes `SIZE` from being a pervasive identifier (declared in the base module). It places `SIZE` in the `SYSTEM` module. It also effects the behaviour of `DIV` and `MOD` operators. See GNU Modula-2 supported dialects.

-fpim3
turn on PIM-3 standard features. Currently this only effects the behaviour of `DIV` and `MOD` operators. See GNU Modula-2 supported dialects.

-fpim4
turn on PIM-4 standard features. Currently this only effects the behaviour of `DIV` and `MOD` operators. See GNU Modula-2 supported dialects.

-fpositive-mod-floor-div
forces the `DIV` and `MOD` operators to behave as defined by PIM4. All modulus results are positive and the results from the division are rounded to the floor. See GNU Modula-2 supported dialects.

-flibs=
modifies the default library search path. The libraries supplied are: m2pim, m2iso, m2min, m2log and m2cor. These map onto the Programming in Modula-2 base libraries, ISO standard libraries, minimal library support, Logitech compatible library and Programming in Modula-2 with coroutines. Multiple libraries can be specified and are comma separated with precidence going to the first in the list. It is not necessary to use -flibs=m2pim or -flibs=m2iso if you also specify -fpim, -fpim2, -fpim3, -fpim4 or -fiso. Unless you are using -flibs=m2min you should include m2pim as the they provide the base modules which all other dialects utilize. The option `-fno-libs=-` disables the `gm2` driver from modifying the search and library paths.

-fextended-opaque
allows opaque types to be implemented as any type. This is a GNU Modula-2 extension and it requires that the implementation module defining the opaque type is available so that it can be resolved when compiling the module which imports the opaque type.

-fsources
displays the path to the source of each module. This option can be used at compile time to check the correct definition module is being used.

-fdef=
recognise the specified suffix as a definition module filename. The default implmentation and module filename suffix is `.def`. If this option is used GNU Modula-2 will still fall back to this default if a requested definition module is not found.

-fmod=
recognise the specified suffix as implementation and module filenames. The default implmentation and module filename suffix is `.mod`. If this option is used GNU Modula-2 will still fall back to this default if it needs to read an implmentation module and the specified suffixed filename does not exist.

-fxcode
issues all errors and warnings in the `Xcode` format.

-funbounded-by-reference
enable optimization of unbounded parameters by attempting to pass non VAR unbounded parameters by reference. This optimization avoids the implicit copy inside the callee procedure. GNU Modula-2 will only allow unbounded parameters to be passed by reference if, inside the callee procedure, they are not written to, no address is calculated on the array and it is not passed as a VAR parameter. Note that it is possible to write code to break this optimization, therefore this option should be used carefully. For example it would be possible to take the address of an array, pass the address and the array to a procedure, read from the array in the procedure and write to the location using the address parameter.

Due to the dangerous nature of this option it is not enabled when the -O option is specified.

-Wverbose-unbounded
inform the user which non VAR unbounded parameters will be passed by reference. This only produces output if the option -funbounded-by-reference is also supplied on the command line.

-Wstyle
checks for poor programming style. This option is aimed at new users of Modula-2 in that it checks for situations which might cause confusion and thus mistakes. It checks whether variables of the same name are declared in different scopes and whether variables look like keywords. Experienced users might find this option too aggressive.

-Wpedantic
forces the compiler to reject nested WITH statements referencing the same record type. Does not allow multiple imports of the same item from a module. It also checks that: procedure variables are written to before being read; variables are not only written to but read from; variables are declared and used. If the compiler encounters a variable being read before written it will terminate with a message. It will check that FOR loop indices are not used outside the end of this loop without being reset.

-Wpedantic-param-names
procedure parameter names are checked in the definition module against their implementation module counterpart. This is not necessary in ISO or PIM versions of Modula-2.

-Wpedantic-cast
warns if the ISO system function is used and if the size of the variable is different from that of the type. This is legal in ISO Modula-2, however it can be dangerous. Some users may prefer to use VAL instead in these situations and use CAST exclusively for changes in type on objects which have the same size.

-Wunused-variable
warns if a variable has been declared and it not used.

-Wunused-parameter
warns if a parameter has been declared and it not used.

-Wall
turn on all Modula-2 warnings.

15.3 GNU Modula-2 related environment variables

This section descibes the environment variables used by GNU Modula-2 and how they can be used to switch between releases of the compiler. Other environment variables can be set to modify the default library path. Initially we will consider environment variables most likely used by the end user. These two environment variables are `GM2IPATH` and `GM2OPATH`.

For example suppose a compile and link on the command line looks like this:

```
$ gm2 -g -c -I. -I../project -I../project/unix foo.mod
$ gm2 -fonlylink -g -I. -I../project -I../project/unix \
  -fobject-path=../project/obj -Iobject-path=../project/unix/obj \
  -I. foo.mod
```

they can be simplified by utilising two environment variables to do exactly the same compile and link.

```
$ export GM2IPATH=../project:../project/unix
$ export GM2OPATH=../project/obj:../project/unix/obj
$ gm2 -g -I. foo.mod
```

It is important to note that the two environment variables `GM2IPATH` and `GM2OPATH` have a lower priority than any `-I` or `-fobject-path=` command line option. The search order for compiling and linking is: command line switches followed by environment variable paths followed by default runtime libraries or Modula-2 dialect libraries. If in doubt include the `-v` option to see the search path used between the compiler subcomponents.

15.4 Elementary data types

This section describes the elementary data types supported by GNU Modula-2. It also describes the relationship between these data types and the equivalent C data types.

The following data types are supported: `INTEGER`, `LONGINT`, `SHORTINT`, `CARDINAL`, `LONGCARD`, `SHORTCARD`, `BOOLEAN`, `REAL`, `LONGREAL`, `SHORTREAL`, `COMPLEX`, `LONGCOMPLEX`, `SHORTCOMPLEX` and `CHAR`.

An equivalence table is given below:

```
GNU Modula-2              GNU C
====================================
INTEGER                   int
LONGINT                   long long int
SHORTINT                  short int
CARDINAL                  unsigned int
LONGCARD                  long long unsigned int
SHORTCARD                 short unsigned int
BOOLEAN                   int
REAL                      double
LONGREAL                  long double
SHORTREAL                 float
```

(continues on next page)

(continued from previous page)

```
CHAR                    char
SHORTCOMPLEX            complex float
COMPLEX                 complex double
LONGCOMPLEX             complex long double
```

Note that GNU Modula-2 also supports fixed sized data types which are exported from the SYSTEM module. See The PIM system module. See The ISO system module.

15.5 Permanently accessible base procedures.

This section describes the procedures and functions which are always visible.

15.5.1 Standard procedures and functions common to PIM and ISO

The following procedures are implemented and conform with Programming in Modula-2 and ISO Modula-2: NEW, DISPOSE, INC, DEC, INCL, EXCL and HALT. The standard functions are: ABS, CAP, CHR, FLOAT, HIGH, LFLOAT, LTRUNC, MIN, MAX, ODD, SFLOAT, STRUNC TRUNC and VAL. All these functions and procedures (except HALT, NEW, DISPOSE and, under non constant conditions, LENGTH) generate in-line code for efficiency.

```
(*
   ABS - returns the positive value of i.
*)

ABS
PROCEDURE ABS (i: <any signed type>) : <any signed type> ;
```

```
(*
   CAP - returns the capital of character ch providing
         ch lies within the range 'a'..'z'. Otherwise ch
         is returned unaltered.
*)

CAP
PROCEDURE CAP (ch: CHAR) : CHAR ;
```

```
(*
   CHR - converts a value of a <whole number type> into a CHAR.
         CHR(x) is shorthand for VAL(CHAR, x).
*)

CHR
PROCEDURE CHR (x: <whole number type>) : CHAR ;
```

```
(*
   DISPOSE - the procedure DISPOSE is replaced by:
```

(continues on next page)

(continued from previous page)

```
            DEALLOCATE(p, TSIZE(p^)) ;
            The user is expected to import the procedure DEALLOCATE
            (normally found in the module, Storage.)

            In:  a variable p: of any pointer type which has been
                 initialized by a call to NEW.
            Out: the area of memory
                 holding p^ is returned to the system.
                 Note that the underlying procedure DEALLOCATE
                 procedure in module Storage will assign p to NIL.
*)

DISPOSE
PROCEDURE DISPOSE (VAR p:<any pointer type>) ;
```

```
(*
   DEC - can either take one or two parameters.  If supplied
         with one parameter then on the completion of the call to
         DEC, v will have its predecessor value.  If two
         parameters are supplied then the value v will have its
         n'th predecessor.  For these reasons the value of n
         must be >=0.
*)

DEC
PROCEDURE DEC (VAR v: <any base type>; [n: <any base type> = 1]) ;
```

```
(*
   EXCL - excludes bit element e from a set type s.
*)

EXCL
PROCEDURE EXCL (VAR s: <any set type>; e: <element of set type s>) ;
```

```
(*
   FLOAT - will return a REAL number whose value is the same as o.
*)

FLOAT
PROCEDURE FLOAT (o: <any whole number type>) : REAL ;
```

```
(*
   FLOATS - will return a SHORTREAL number whose value is the same as o.
*)

FLOATS
PROCEDURE FLOATS (o: <any whole number type>) : REAL ;
```

```
(*
   FLOATL - will return a LONGREAL number whose value is the same as o.
```

(continues on next page)

(continued from previous page)

```
*)

FLOATL
PROCEDURE FLOATL (o: <any whole number type>) : REAL ;
```

```
(*
   HALT - will call the HALT procedure inside the module M2RTS.
          Users can replace M2RTS.
*)

HALT
PROCEDURE HALT ;
```

```
(*
   HIGH - returns the last accessible index of an parameter declared as
          ARRAY OF CHAR. Thus

          PROCEDURE foo (a: ARRAY OF CHAR) ;
          VAR
             c: CARDINAL ;
          BEGIN
             c := HIGH(a)
          END foo ;

          BEGIN
             foo('hello')
          END

          will cause the local variable c to contain the value 4
*)

HIGH
PROCEDURE HIGH (a: ARRAY OF CHAR) : CARDINAL ;
```

```
(*
   INC - can either take one or two parameters.  If supplied
         with one parameter then on the completion of the call to
         INC, v will have its successor value.  If two
         parameters are supplied then the value v will have its
         n'th successor.  For these reasons the value of n
         must be >=0.
*)

INC
PROCEDURE INC (VAR v: <any base type>; [n: <any base type> = 1]) ;
```

```
(*
   INCL - includes bit element e to a set type s.
*)
```

(continues on next page)

(continued from previous page)

            as o.
*)

SFLOAT
PROCEDURE SFLOAT (o: <any whole number type>) : SHORTREAL ;
```

```
(*
   STRUNC - will return a SHORT<type> number whose value is the same
            as o.  PIM2, PIM3 and ISO Modula-2 will return a
            SHORTCARD whereas PIM4 returns SHORTINT.
*)

STRUNC
PROCEDURE STRUNC (o: <any floating point type>) : SHORT<type> ;
```

```
(*
   TRUNC - will return a <type> number whose value is the same as o.
           PIM2, PIM3 and ISO Modula-2 will return a CARDINAL
           whereas PIM4 returns INTEGER.
*)

TRUNC
PROCEDURE TRUNC (o: <any floating point type>) : <type> ;
```

```
(*
   TRUNCS - will return a <type> number whose value is the same
            as o.  PIM2, PIM3 and ISO Modula-2 will return a
            SHORTCARD whereas PIM4 returns SHORTINT.
*)

TRUNCS
PROCEDURE TRUNCS (o: <any floating point type>) : <type> ;
```

```
(*
   TRUNCL - will return a <type> number whose value is the same
            as o.  PIM2, PIM3 and ISO Modula-2 will return a
            LONGCARD whereas PIM4 returns LONGINT.
*)

TRUNCL
PROCEDURE TRUNCL (o: <any floating point type>) : <type> ;
```

```
(*
   VAL - converts data i of <any simple data type 2> to
         <any simple data type 1> and returns this value.
         No range checking is performed during this conversion.
*)

VAL
PROCEDURE VAL (<any simple data type 1>,
               i: <any simple data type 2>) : <any simple data type 1> ;
```

15.5.2 ISO specific standard procedures and functions

The standard function `LENGTH` is specific to ISO Modula-2 and is defined as:

```
(*
   IM - returns the imaginary component of a complex type.
        The return value will the same type as the imaginary field
        within the complex type.
*)

IM
PROCEDURE IM (c: <any complex type>) : <floating point type> ;
```

```
(*
   INT - returns an INTEGER value which has the same value as v.
         This function is equivalent to: VAL(INTEGER, v).
*)

INT
PROCEDURE INT (v: <any ordinal type>) : INTEGER ;
```

```
(*
   LENGTH - returns the length of string a.
*)

LENGTH
PROCEDURE LENGTH (a: ARRAY OF CHAR) : CARDINAL ;
```

This function is evaluated at compile time, providing that string `a` is a constant. If `a` cannot be evaluated then a call is made to `M2RTS.Length`.

```
(*
   ODD - returns a BOOLEAN indicating whether the whole number
         value, v, is odd.
*)

ODD
PROCEDURE ODD (v: <any whole number type>) : BOOLEAN ;
```

```
(*
   RE - returns the real component of a complex type.
        The return value will the same type as the real field
        within the complex type.
*)

RE
PROCEDURE RE (c: <any complex type>) : <floating point type> ;
```

15.6 GNU Modula-2 supported dialects

This section describes the dialects understood by GNU Modula-2. It also describes the differences between the dialects and any command line switches which determine dialect behaviour.

The GNU Modula-2 compiler is compliant with four dialects of Modula-2. The language as defined in 'Programming in Modula-2' 2nd Edition, Springer Verlag, 1982, 1983 by Niklaus Wirth (PIM2), 'Programming in Modula-2', 3rd Corrected Edition, Springer Verlag, 1985 (PIM3) and 'Programming in Modula-2', 4th Edition, Springer Verlag, 1988 (PIM4) http://freepages.modula2.org/report4/modula-2.html and the ISO Modula-2 language as defined in ISO/IEC Information technology - programming languages - part 1: Modula-2 Language, ISO/IEC 10514-1 (1996) (ISO).

The command line switches `-fpim2`, `-fpim3`, `-fpim4` and `-fiso` can be used to force mutually exclusive features. However by default the compiler will not aggressively fail if a non mutually exclusive feature is used from another dialect. For example it is possible to specify `-fpim2` and still utilise `DEFINITION MODULES` which have no export list.

Some dialect differences will force a compile time error, for example in PIM2 the user must `IMPORT SIZE` from the module `SYSTEM`, whereas in PIM3 and PIM4 `SIZE` is a pervasive function. Thus compiling PIM4 source code with the `-fpim2` switch will cause a compile time error. This can be fixed quickly with an additional `IMPORT` or alternatively by compiling with the `-fpim4` switch.

However there are some very important differences between the dialects which are mutually exclusive and therefore it is vital that users choose the dialects with care when these language features are used.

15.6.1 Integer division, remainder and modulus

The most dangerous set of mutually exclusive features found in the four dialects supported by GNU Modula-2 are the `INTEGER` division, remainder and modulus arithmetic operators. It is important to note that the same source code can be compiled to give different runtime results depending upon these switches! The reference manual for the various dialects of Modula-2 are quite clear about this behaviour and sadly there are three distinct definitions.

The table below illustrates the problem when a negative operand is used.

```
                 Pim2/3          Pim4               ISO
               -----------    -----------    ----------------------
lval    rval   DIV     MOD    DIV     MOD    DIV    MOD    /    REM
```

(continues on next page)

(continued from previous page)

```
 31      10      3       1      3       1      3      1     3     1
-31      10     -3      -1     -4       9     -4      9    -3    -1
 31     -10     -3       1     -3       1     Exception    -3     1
-31     -10      3      -1      4       9     Exception     3    -1
```

See also P24 of PIM2, P27 of PIM3, P29 of PIM4 and P201 of the ISO Standard. At present all dialect division, remainder and modulus are implemented as above, apart from the exception calling in the ISO dialect. Instead of exception handling the results are the same as the PIM4 dialect. This is a temporary implementation situation.

15.7 Exception implementation

This section describes how exceptions are implemented in GNU Modula-2 and how command line switches affect their behaviour. The option `-fsoft-check-all` enables all software checking of nil dereferences, division by zero etc. Additional code is produced to check these conditions and exception handlers are invoked if the conditions prevail.

Without `-fsoft-check-all` these exceptions will be caught by hardware (assuming the hardware support exists) and a signal handler is invoked. The signal handler will in turn `THROW` an exception which will be caught by the appropriate Modula-2 handler. However the action of throwing an exception from within a signal handler is implementation defined (according to the C++ documentation). For example on the x86_64 architecture this works whereas on the i686 architecture it does not. Therefore to ensure portability it is recommended to use `-fsoft-check-all`.

`-fsoft-check-all` can be effectively combined with `-O2` to semantically analyse source code for possible runtime errors at compile time.

15.8 How to detect runtime problems at compile time

Consider the following program:

```
MODULE assignvalue ;  (*!m2iso+gm2*)

PROCEDURE bad () : INTEGER ;
VAR
   i: INTEGER ;
BEGIN
   i := -1 ;
   RETURN i
END bad ;

VAR
   foo: CARDINAL ;
BEGIN
   (* the m2rte plugin will detect this as an error, post
      optimization.  *)
```

(continues on next page)

(continued from previous page)

```
   foo := bad ()
END assignvalue.
```

here we see that the programmer has overlooked that the return value from `bad` will cause an overflow to `foo`. If we compile the code with the following options:

```
$ gm2 -g -fsoft-check-all -O2 -c assignvalue.mod
assignvalue.mod:16:0:inevitable that this error will occur at runtime,
assignment will result in an overflow
```

The gm2 semantic plugin is automatically run and will generate a warning message for every exception call which is known as reachable. It is highly advised to run the optimizer (`-O2` or `-O3`) with `-fsoft-check-all` so that the compiler is able to run the optimizer and perform variable and flow analysis before the semantic plugin is invoked.

15.9 GNU Modula-2 language extensions

This section introduces the GNU Modula-2 language extensions. The GNU Modula-2 compiler allows abstract data types to be any type, not just restricted to a pointer type providing the `-fextended-opaque` option is supplied See Compiler options.

Declarations can be made in any order, whether they are types, constants, procedures, nested modules or variables.

GNU Modula-2 also allows programmers to interface to `C` and assembly language.

GNU Modula-2 provides support for the special tokens `__LINE__`, `__FILE__`, `__FUNCTION__` and `__DATE__`. Support for these tokens will occur even if the `-fcpp` option is not supplied. A table of these identifiers and their data type and values is given below:

```
Scope       GNU Modula-2 token      Data type and example value

anywhere    __LINE__                Constant Literal compatible
                                    with CARDINAL, INTEGER and WORD.
                                    Example 1234

anywhere    __FILE__                Constant string compatible
                                    with parameter ARRAY OF CHAR or
                                    an ARRAY whose SIZE is >= string
                                    length. Example
                                    "hello.mod"

procedure   __FUNCTION__            Constant string compatible
                                    with parameter ARRAY OF CHAR or
                                    an ARRAY whose SIZE is >= string
                                    length. Example
                                    "calc"

module      __FUNCTION__            Example
```

(continues on next page)

(continued from previous page)

```
                                "module hello initialization"

anywhere    __DATE__            Constant string compatible
                                with parameter ARRAY OF CHAR or
                                an ARRAY whose SIZE is >= string
                                length. Example
                                "Thu Apr 29 10:07:16 BST 2004"

anywhere    __COLUMN__          Gives a contant literal number
                                determining the left hand column
                                where the first _ appears in
                                __COLUMN__.  The left most column
                                is 1.
```

The preprocessor `cpp` can be invoked via the `-fcpp` command line option. This in turn invokes `cpp` with the following arguments `-traditional -lang-asm`. These options preserve comments and all quotations. `gm2` treats a `#` character in the first column as a preprocessor directive.

For example here is a module which calls `FatalError` via the macro `ERROR`.

```
MODULE cpp ;

FROM SYSTEM IMPORT ADR, SIZE ;
FROM libc IMPORT exit, printf, malloc ;

PROCEDURE FatalError (a, file: ARRAY OF CHAR;
                      line: CARDINAL;
                      func: ARRAY OF CHAR) ;
BEGIN
   printf("%s:%d:fatal error, %s, in %s\n",
          ADR(file), line, ADR(a), ADR(func)) ;
   exit(1)
END FatalError ;

#define ERROR(X)  FatalError(X, __FILE__, __LINE__, __FUNCTION__)

VAR
   pc: POINTER TO CARDINAL;
BEGIN
   pc := malloc(SIZE(CARDINAL)) ;
   IF pc=NIL
   THEN
      ERROR('out of memory')
   END
END cpp.
```

Another use for the C preprocessor in Modula-2 might be to turn on debugging code. For example the library module `FormatStrings.mod` uses procedures from `DynamicStrings.mod` and to track down memory leaks it was useful to track the source file and line where each string was created. Here is a section of `FormatStrings.mod` which shows how the debugging code was enabled and disabled by adding `-fcpp` to the command line.

```
FROM DynamicStrings IMPORT String, InitString, InitStringChar, Mark,
                           ConCat, Slice, Index, char,
                           Assign, Length, Mult, Dup, ConCatChar,
                           PushAllocation, PopAllocationExemption,
                           InitStringDB, InitStringCharStarDB,
                           InitStringCharDB, MultDB, DupDB, SliceDB ;

(*
#define InitString(X) InitStringDB(X, __FILE__, __LINE__)
#define InitStringCharStar(X) InitStringCharStarDB(X, __FILE__, \
                                                   __LINE__)
#define InitStringChar(X) InitStringCharDB(X, __FILE__, __LINE__)
#define Mult(X,Y) MultDB(X, Y, __FILE__, __LINE__)
#define Dup(X) DupDB(X, __FILE__, __LINE__)
#define Slice(X,Y,Z) SliceDB(X, Y, Z, __FILE__, __LINE__)
*)

PROCEDURE doDSdbEnter ;
BEGIN
   PushAllocation
END doDSdbEnter ;

PROCEDURE doDSdbExit (s: String) ;
BEGIN
   s := PopAllocationExemption(TRUE, s)
END doDSdbExit ;

PROCEDURE DSdbEnter ;
BEGIN
END DSdbEnter ;

PROCEDURE DSdbExit (s: String) ;
BEGIN
END DSdbExit ;

(*
#define DBsbEnter doDBsbEnter
#define DBsbExit  doDBsbExit
*)

PROCEDURE Sprintf1 (s: String; w: ARRAY OF BYTE) : String ;
BEGIN
   DSdbEnter ;
   s := FormatString(HandleEscape(s), w) ;
   DSdbExit(s) ;
   RETURN( s )
END Sprintf1 ;
```

It is worth noting that the overhead of this code once `-fcpp` is not present and -O2 is used will be zero since the local empty procedures `DSdbEnter` and `DSdbExit` will be thrown away by the optimization passes of the GCC backend.

15.9.1 Optional procedure parameter

GNU Modula-2 allows the last parameter to a procedure or function parameter to be optional. For example in the ISO library `COROUTINES.def` the procedure `NEWCOROUTINE` is defined as having an optional fifth argument (`initProtection`) which, if absent, is automatically replaced by `NIL`.

```
NEWCOROUTINE
PROCEDURE NEWCOROUTINE (procBody: PROC; workspace: SYSTEM.ADDRESS;
                        size: CARDINAL; VAR cr: COROUTINE;
                        [initProtection: PROTECTION = NIL]);

  (* Creates a new coroutine whose body is given by procBody,
     and returns the identity of the coroutine in cr.
     workspace is a pointer to the work space allocated to
     the coroutine; size specifies the size of this workspace
     in terms of SYSTEM.LOC.

     The optional fifth argument may contain a single parameter
     which specifies the initial protection level of the coroutine.
  *)
```

The implementation module `COROUTINES.mod` implements this procedure using the following syntax:

```
PROCEDURE NEWCOROUTINE (procBody: PROC; workspace: SYSTEM.ADDRESS;
                        size: CARDINAL; VAR cr: COROUTINE;
                        [initProtection: PROTECTION]);
BEGIN

END NEWCOROUTINE ;
```

Note that it is illegal for this declaration to contain an initialiser value for `initProtection`. However it is necessary to surround this parameter with the brackets `[` and `]`. This serves to remind the programmer that the last parameter was declared as optional in the definition module.

Local procedures can be declared to have an optional final parameter in which case the initializer is mandatory in the implementation or program module.

GNU Modula-2 also provides additional fixed sized data types which are all exported from the `SYSTEM` module. See The PIM system module. See The ISO system module.

15.10 Type compatibility

This section discuss the issues surrounding assignment, expression and parameter compatibility, their effect of the additional fixed sized datatypes and also their effect of runtime checking. The data types supported by the compiler are:

```
GNU Modula-2              scope      switches
=========================================
INTEGER                   pervasive
LONGINT                   pervasive
```

(continues on next page)

(continued from previous page)

```
SHORTINT                pervasive
CARDINAL                pervasive
LONGCARD                pervasive
SHORTCARD               pervasive
BOOLEAN                 pervasive
BITSET                  pervasive
REAL                    pervasive
LONGREAL                pervasive
SHORTREAL               pervasive
CHAR                    pervasive
SHORTCOMPLEX            pervasive
COMPLEX                 pervasive
LONGCOMPLEX             pervasive

LOC                     SYSTEM     -fiso
BYTE                    SYSTEM
WORD                    SYSTEM
ADDRESS                 SYSTEM

The following extensions are supported for
most architectures (please check SYSTEM.def).
=============================================
INTEGER8                SYSTEM
INTEGER16               SYSTEM
INTEGER32               SYSTEM
INTEGER64               SYSTEM
CARDINAL8               SYSTEM
CARDINAL16              SYSTEM
CARDINAL32              SYSTEM
CARDINAL64              SYSTEM
BITSET8                 SYSTEM
BITSET16                SYSTEM
BITSET32                SYSTEM
WORD16                  SYSTEM
WORD32                  SYSTEM
WORD64                  SYSTEM
REAL32                  SYSTEM
REAL64                  SYSTEM
REAL96                  SYSTEM
REAL128                 SYSTEM
COMPLEX32               SYSTEM
COMPLEX64               SYSTEM
COMPLEX96               SYSTEM
COMPLEX128              SYSTEM
```

The Modula-2 language categorises compatibility between entities of possibly differing types into three subcomponents: expressions, assignments, and parameters. Parameter compatibility is further divided into two sections for pass by reference and pass by value compatibility.

For more detail on the Modula-2 type compatibility see the Modula-2 ISO standard BS ISO/IEC 10514-1:1996 page 121-125. For detail on the PIM type compatibility see Programming in Modula-2 Edition 4 page 29, (Elementary Data Types).

15.10.1 Expression compatibility

Modula-2 restricts the types of expressions to the same type. Expression compatibility is a symmetric relation.

For example two sub expressions of `INTEGER` and `CARDINAL` are not expression compatible (http://freepages.modula2.org/report4/modula-2.html and ISO Modula-2).

In GNU Modula-2 this rule is also extended across all fixed sized data types (imported from SYSTEM).

15.10.2 Assignment compatibility

This section discusses the assignment issues surrounding assignment compatibility of elementary types (`INTEGER`, `CARDINAL`, `REAL` and `CHAR` for example). The information here is found in more detail in the Modula-2 ISO standard BS ISO/IEC 10514-1:1996 page 122.

Assignment compatibility exists between the same sized elementary types.

Same type family of different sizes are also compatible as long as the `MAX(` type `)` and `MIN(` type `)` is known. So for example this includes the `INTEGER` family, `CARDINAL` family and the `REAL` family.

The reason for this is that when the assignment is performed the compiler will check to see that the expression (on the right of the `:=`) lies within the range of the designator type (on the left hand side of the `:=`). Thus these ordinal types can be assignment compatible. However it does mean that `WORD32` is not compatible with `WORD16` as `WORD32` does not have a minimum or maximum value and therefore cannot be checked. The compiler does not know which of the two bytes from `WORD32` should be copied into `WORD16` and which two should be ignored. Currently the types `BITSET8`, `BITSET16` and `BITSET32` are assignment incompatible. However this restriction maybe lifted when further runtime checking is achieved.

Modula-2 does allow `INTEGER` to be assignment compatible with `WORD` as they are the same size. Likewise GNU Modula-2 allows `INTEGER16` to be compatible with `WORD16` and the same for the other fixed sized types and their sized equivalent in either `WORD` n, `BYTE` or `LOC` types. However it prohibits assignment between `WORD` and `WORD32` even though on many systems these sizes will be the same. The reasoning behind this rule is that the extended fixed sized types are meant to be used by applications requiring fixed sized data types and it is more portable to forbid the bluring of the boundaries between fixed sized and machine dependant sized types.

Intemediate code runtime checking is always generated by the front end. However this intemediate code is only translated into actual code if the appropriate command line switches are specified. This allows the compiler to perform limited range checking at compile time. In the future it will allow the extensive GCC optimisations to propagate constant values through to the range checks which if they are found to exceed the type range will result in a compile time error message.

15.10.3 Parameter compatibility

Parameter compatibility is divided into two areas, pass by value and pass by reference (`VAR`). In the case of pass by value the rules are exactly the same as assignment. However in the second case, pass by reference, the actual parameter and formal parameter must be the same size and family. Furthermore `INTEGER` and `CARDINAL` s are not treated as compatible in the pass by reference case.

The types `BYTE`, `LOC`, `WORD` and `WORD` n derivitives are assignment and parameter compatible with any data type of the same size.

15.11 Unbounded by reference

This section documents a GNU Modula-2 compiler switch which implements a language optimisation surrounding the implementation of unbounded arrays. In GNU Modula-2 the unbounded array is implemented by utilising an internal structure `struct {dataType *address, unsigned int high}`. So given the Modula-2 procedure declaration:

```
PROCEDURE foo (VAR a: ARRAY OF dataType) ;
BEGIN
   IF a[2]= (* etc *)
END foo ;
```

it is translated into GCC `tree` s, which can be represented in their C form thus:

```
void foo (struct {dataType *address, unsigned int high} a)
{
   if (a.address[2] == /* etc */
}
```

Whereas if the procedure `foo` was declared as:

```
PROCEDURE foo (a: ARRAY OF dataType) ;
BEGIN
   IF a[2]= (* etc *)
END foo ;
```

then it is implemented by being translated into the following GCC `tree` s, which can be represented in their C form thus:

```
void foo (struct {dataType *address, unsigned int high} a)
{
   dataType *copyContents = (dataType *)alloca (a.high+1);
   memcpy(copyContents, a.address, a.high+1);
   a.address = copyContents;

   if (a.address[2] == /* etc */
}
```

This implementation works, but it makes a copy of each non VAR unbounded array when a procedure is entered. If the unbounded array is not changed during procedure `foo` then this imple-

mentation will be very inefficient. In effect Modula-2 lacks the `REF` keyword of Ada. Consequently the programmer maybe tempted to sacrifice semantic clarity for greater efficiency by declaring the parameter using the `VAR` keyword in place of `REF`.

The `-funbounded-by-reference` switch instructs the compiler to check and see if the programmer is modifying the content of any unbounded array. If it is modified then a copy will be made upon entry into the procedure. Conversely if the content is only read and never modified then this non `VAR` unbounded array is a candidate for being passed by reference. It is only a candidate as it is still possible that passing this parameter by reference could alter the meaning of the source code. For example consider the following case:

```
PROCEDURE StrConCat (VAR a: ARRAY OF CHAR; b, c: ARRAY OF CHAR) ;
BEGIN
   (* code which performs string a := b + c *)
END StrConCat ;

PROCEDURE foo ;
VAR
   a: ARRAY [0..3] OF CHAR ;
BEGIN
   a := 'q' ;
   StrConCat(a, a, a)
END foo ;
```

In the code above we see that the same parameter, `a`, is being passed three times to `StrConCat`. Clearly even though parameters `b` and `c` are never modified it would be incorrect to implement them as pass by reference. Therefore the compiler checks to see if any non `VAR` parameter is type compatible with any `VAR` parameter and if so it generates runtime procedure entry checks to determine whether the contents of parameters `b` or `c` matches the contents of `a`. If a match is detected then a copy is made and the `address` in the unbounded `struct` ure is modified.

The compiler will check the address range of each candidate against the address range of any `VAR` parameter, providing they are type compatible. For example consider:

```
PROCEDURE foo (a: ARRAY OF BYTE; VAR f: REAL) ;
BEGIN
   f := 3.14 ;
   IF a[0]=BYTE(0)
   THEN
      (* etc *)
   END
END foo ;

PROCEDURE bar ;
BEGIN
   r := 2.0 ;
   foo(r, r)
END bar ;
```

Here we see that although parameter, `a`, is a candidate for the passing by reference, it would be incorrect to use this transformation. Thus the compiler detects that parameters, `a` and `f` are type compatible and will produce runtime checking code to test whether the address range of their

respective contents intersect.

This section describes the linking related options. There are three linking strategies available which are dynamic scaffold, static scaffold and user defined. The dynamic scaffold is enabled by default and each module will register itself to the runtime `M2RTS` via a constructor. The static scaffold mechanism will invoke each modules `_init` and `_finish` function in turn via a sequence of calls from within `main`. Lastly the user defined strategy can be implemented by turning off the dynamic and static options via `-fno-scaffold-dynamic` and `-fno-scaffold-static`.

In the simple test below:

```
$ gm2 hello.mod
```

the driver will add the options `-fscaffold-dynamic` and `-fgen-module-list=-` which generate a list of application modules and also creates the `main` function with calls to `M2RTS`. It can be useful to add the option `-fsources` which displays the source files as they are parsed and summarizes whether the source file is required for compilation or linking.

If you wish to split the above command line into a compile and link then you could use these steps:

```
$ gm2 -c -fscaffold-main hello.mod
$ gm2 hello.o
```

The `-fscaffold-main` informs the compiler to generate the `main` function and scaffold. You can enable the environment variable `GCC_M2LINK_RTFLAG` to trace the construction and destruction of the application. The values for `GCC_M2LINK_RTFLAG` are shown in the table below:

```
value   | meaning
================
all     | turn on all flags below
module  | trace modules as they register themselves
pre     | generate module list prior to dependency resolution
dep     | trace module dependency resolution
post    | generate module list after dependency resolution
force   | generate a module list after dependency and forced
        | ordering is complete
```

The values can be combined using a comma separated list.

One of the advantages of the dynamic scaffold is that the driver behaves in a similar way to the other front end drivers. For example consider a small project consisting of 4 definition implementation modules (`a.def`, `a.mod`, `b.def`, `b.mod`, `c.def`, `c.mod`, `d.def`, `d.mod`) and a program module `program.mod`.

To link this project we could:

```
$ gm2 -g -c a.mod
$ gm2 -g -c b.mod
$ gm2 -g -c c.mod
$ gm2 -g -c d.mod
$ gm2 -g program.mod a.o b.o c.o d.o
```

The module initialization sequence is defined by the ISO standard to follow the import graph

traversal. The initialization order is the order in which the corresponding separate modules finish the processing of their import lists.

However, if required, you can override this using `-fruntime-modules=a,b,c,d` for example which forces the initialization sequence to `a`, `b`, `c` and `d`.

15.12 Building a shared library

This section describes building a tiny shared library implemented in Modula-2 and built with `libtool`. Suppose a project consists of two definition modules and two implementation modules and a program module `a.def`, `a.mod`, `b.def`, `b.mod` and `c.mod`. The first step is to compile the modules using position independent code. This can be achieved by the following three commands:

```
libtool --tag=CC --mode=compile gm2 -g -c a.mod -o a.lo
libtool --tag=CC --mode=compile gm2 -g -c b.mod -o b.lo
libtool --tag=CC --mode=compile gm2 -g -c c.mod -o c.lo
```

The second step is to generate the shared library initialization and finalization routines. We can do this by asking gm2 to generate a list of dependant modules and then use this to generate the scaffold. We also must compile the scaffold.

```
gm2 -c -g -fmakelist c.mod
gm2 -c -g -fmakeinit -fshared c.mod
libtool --tag=CC --mode=compile g++ -g -c c_m2.cpp -o c_m2.lo
```

The third step is to link all these `.lo` files.

```
libtool --mode=link gcc -g c_m2.lo a.lo b.lo c.lo \
        -L$(prefix)/lib64 \
        -rpath `pwd` -lgm2 -lstdc++ -lm -o libabc.la
```

At this point the shared library `libabc.so` will have been created inside the directory `.libs`.

15.13 How to produce swig interface files

This section describes how Modula-2 implementation modules can be called from Python (and other scripting languages such as TCL and Perl). GNU Modula-2 can be instructed to create a swig interface when it is compiling an implementation module. Swig then uses the interface file to generate all the necessary wrapping to that the desired scripting language may access the implementation module.

Here is an example of how you might call upon the services of the Modula-2 library module `NumberIO` from Python3.

The following commands can be used to generate the Python3 module:

```
export src=directory to the sources
export prefix=directory to where the compiler is installed
gm2 -I${src} -c -g -fswig ${src}/../../../gm2-libs/NumberIO.mod
gm2 -I${src} -c -g -fmakelist ${src}/../../../gm2-libs/NumberIO.mod

gm2 -I${src} -c -g -fmakeinit -fshared \
   ${src}/../../../gm2-libs/NumberIO.mod

swig -c++ -python3 NumberIO.i

libtool --mode=compile g++ -g -c -I${src} NumberIO_m2.cpp \
  -o NumberIO_m2.lo

libtool --tag=CC --mode=compile gm2 -g -c \
  -I${src}../../../gm2-libs \
  ${src}/../../../gm2-libs/NumberIO.mod -o NumberIO.lo

libtool --tag=CC --mode=compile g++ -g -c NumberIO_wrap.cxx \
  -I/usr/include/python3 -o NumberIO_wrap.lo

libtool --mode=link gcc -g NumberIO_m2.lo NumberIO_wrap.lo \
   -L${prefix}/lib64 \
   -rpath `pwd` -lgm2 -lstdc++ -lm -o libNumberIO.la

cp .libs/libNumberIO.so _NumberIO.so
```

The first four commands, generate the swig interface file `NumberIO.i` and python wrap files `NumberIO_wrap.cxx` and `NumberIO.py`. The next three `libtool` commnads compile the C++ and Modula-2 source code into `.lo` objects. The last `libtool` command links all the `.lo` files into a `.la` file and includes all shared library dependencies.

Now it is possible to run the following Python script (called `testnum.py`):

```
import NumberIO

print ("1234 x 2 =", NumberIO.NumberIO_StrToInt("1234")*2)
```

like this:

```
$ python3 testnum.py
1234 x 2 = 2468
```

See How to produce a Python module for another example which uses the `UNQUALIFIED` keyword to reduce the module name clutter from the viewport of Python3.

15.13.1 Limitations of automatic generated of Swig files

This section discusses the limitations of automatically generating swig files. From the previous example we see that the module `NumberIO` had a swig interface file `NumberIO.i` automatically generated by the compiler. If we consider three of the procedure definitions in `NumberIO.def` we can see the success and limitations of the automatic interface generation.

```
PROCEDURE StrToHex (a: ARRAY OF CHAR; VAR x: CARDINAL) ;
PROCEDURE StrToInt (a: ARRAY OF CHAR; VAR x: INTEGER) ;
PROCEDURE ReadInt (VAR x: CARDINAL) ;
```

Below are the swig interface prototypes:

```
extern void NumberIO_StrToHex (char *_m2_address_a,
                               int _m2_high_a, unsigned int *OUTPUT);
/*  parameters: x is known to be an OUTPUT */
extern void NumberIO_StrToInt (char *_m2_address_a,
                               int _m2_high_a, int *OUTPUT);
/*  parameters: x is guessed to be an OUTPUT */
extern void NumberIO_ReadInt (int *x);
/*  parameters: x is unknown */
```

In the case of `StrToHex` it can be seen that the compiler detects that the last parameter is an output. It explicitly tells swig this by using the parameter name `OUTPUT` and in the following comment it informs the user that it knows this to be an output parameter. In the second procedure `StrToInt` it marks the final parameter as an output, but it tells the user that this is only a guess. Finally in `ReadInt` it informs the user that it does not know whether the parameter, `x`, is an output, input or an inout parameter.

The compiler decides whether to mark a parameter as either: `INPUT`, `OUTPUT` or `INOUT` if it is read before written or visa versa in the first basic block. At this point it will write output that the parameter is known. If it is not read or written in the first basic block then subsequent basic blocks are searched and the result is commented as a guess. Finally if no read or write occurs then the parameter is commented as unknown. However, clearly it is possible to fool this mechanism. Nevertheless automatic generation of implementation module into swig interface files was thought sufficiently useful despite these limitations.

In conclusion it would be wise to check all parameters in any automatically generated swig interface file. Furthermore you can force the automatic mechanism to generate correct interface files by reading or writing to the `VAR` parameter in the first basic block of a procedure.

15.14 How to produce a Python module

This section descibes how it is possible to produce a Python module from Modula-2 code. There are a number of advantages to this approach, it ensures your code reaches a wider audience, maybe it is easier to initialize your application in Python.

The example application here is a pedagogical two dimensional gravity next event simulation. The Python module needs to have a clear API which should be placed in a single definition module.

Furthermore the API should only use fundamental pervasive data types and strings. Below the API is contained in the file `twoDsim.def`:

```
DEFINITION MODULE twoDsim ;

EXPORT UNQUALIFIED gravity, box, poly3, poly5, poly6, mass,
                   fix, circle, pivot, velocity, accel, fps,
                   replayRate, simulateFor ;
(*
   gravity - turn on gravity at: g m^2
*)

PROCEDURE gravity (g: REAL) ;

(*
   box - place a box in the world at (x0,y0),(x0+i,y0+j)
*)

PROCEDURE box (x0, y0, i, j: REAL) : CARDINAL ;

(*
   poly3 - place a triangle in the world at:
           (x0,y0),(x1,y1),(x2,y2)
*)

PROCEDURE poly3 (x0, y0, x1, y1, x2, y2: REAL) : CARDINAL ;

(*
   poly5 - place a pentagon in the world at:
           (x0,y0),(x1,y1),(x2,y2),(x3,y3),(x4,y4)
*)

PROCEDURE poly5 (x0, y0, x1, y1,
                 x2, y2, x3, y3, x4, y4: REAL) : CARDINAL ;

(*
   poly6 - place a hexagon in the world at:
           (x0,y0),(x1,y1),(x2,y2),(x3,y3),(x4,y4),(x5,y5)
*)

PROCEDURE poly6 (x0, y0, x1, y1,
                 x2, y2, x3, y3,
                 x4, y4, x5, y5: REAL) : CARDINAL ;

(*
   mass - specify the mass of an object and return the, id.
*)

PROCEDURE mass (id: CARDINAL; m: REAL) : CARDINAL ;

(*
   fix - fix the object to the world.
*)
```

(continues on next page)

(continued from previous page)

```
PROCEDURE fix (id: CARDINAL) : CARDINAL ;

(*
   circle - adds a circle to the world.  Center
            defined by: x0, y0 radius, r.
*)

PROCEDURE circle (x0, y0, r: REAL) : CARDINAL ;

(*
   velocity - give an object, id, a velocity, vx, vy.
*)

PROCEDURE velocity (id: CARDINAL; vx, vy: REAL) : CARDINAL ;

(*
   accel - give an object, id, an acceleration, ax, ay.
*)

PROCEDURE accel (id: CARDINAL; ax, ay: REAL) : CARDINAL ;

(*
   fps - set frames per second.
*)

PROCEDURE fps (f: REAL) ;

(*
   replayRate - set frames per second during replay.
*)

PROCEDURE replayRate (f: REAL) ;

(*
   simulateFor - render for, t, seconds.
*)

PROCEDURE simulateFor (t: REAL) ;

END twoDsim.
```

The keyword `UNQUALIFIED` can be used to ensure that the compiler will provide externally accessible functions `gravity`, `box`, `poly3`, `poly5`, `poly6`, `mass`, `fix`, `circle`, `pivot`, `velocity`, `accel`, `fps`, `replayRate`, `simulateFor` rather than name mangled alternatives. Hence in our Python3 application we could write:

```
#!/usr/bin/env python3

from twoDsim import *
```

(continues on next page)

(continued from previous page)

```
b = box (0.0, 0.0, 1.0, 1.0)
b = fix (b)
c1 = circle (0.7, 0.7, 0.05)
c1 = mass (c1, 0.01)
c2 = circle (0.7, 0.1, 0.05)
c2 = mass (c2, 0.01)
c2 = fix (c2)
gravity (-9.81)
fps (24.0*4.0)
replayRate (24.0)
print ("creating frames")
try:
    simulateFor (1.0)
    print ("all done")
except:
    print ("exception raised")
```

which accesses the various functions defined and implemented by the module `twoDsim`. The Modula-2 source code is compiled via:

```
$ gm2 -g -fiso -c -fswig twoDsim.mod
$ gm2 -g -fiso -c -fmakelist twoDsim.mod
$ gm2 -g -fiso -c -fmakeinit twoDsim.mod
```

The first command both compiles the source file creating `twoDsim.o` and produces a swig interface file `swig.i`. We now use `swig` and `g++` to produce and compile the interface wrappers:

```
$ libtool --mode=compile g++ -g -c twoDsim_m2.cpp -o twoDsim_m2.lo
$ swig -c++ -python3 twoDsim.i
$ libtool --mode=compile g++ -c -fPIC twoDsim_wrap.cxx \
   -I/usr/include/python3 -o twoDsim_wrap.lo
$ libtool --mode=compile gm2 -g -fPIC -fiso -c deviceGnuPic.mod
$ libtool --mode=compile gm2 -g -fPIC -fiso -c roots.mod
$ libtool --mode=compile gm2 -g -fPIC -fiso -c -fswig \
   twoDsim.mod -o twoDsim.lo
```

Finally the application is linked into a shared library:

```
$ libtool --mode=link gcc -g twoDsim_m2.lo twoDsim_wrap.lo \
  roots.lo deviceGnuPic.lo \
   -L${prefix}/lib64 \
   -rpath `pwd` -lgm2 -lstdc++ -lm -o libtwoDsim.la
cp .libs/libtwoDsim.so _twoDsim.so
```

The library name must start with `_` to comply with the Python3 module naming scheme.

15.15 Interfacing GNU Modula-2 to C

The GNU Modula-2 compiler tries to use the C calling convention wherever possible however some parameters have no C equivalent and thus a language specific method is used. For example unbounded arrays are passed as a `struct {void *address, unsigned int high}` and the contents of these arrays are copied by callee functions when they are declared as non `VAR` parameters. The `VAR` equivalent unbounded array parameters need no copy, but still use the `struct` representation.

The recommended method of interfacing GNU Modula-2 to C is by telling the definition module that the implementation is in the C language. This is achieved by using the tokens `DEFINITION MODULE FOR "C"`. Here is an example `libprintf.def`.

```
DEFINITION MODULE FOR "C" libprintf ;

EXPORT UNQUALIFIED printf ;

PROCEDURE printf (a: ARRAY OF CHAR; ...) : [ INTEGER ] ;

END libprintf.
```

the `UNQUALIFIED` keyword in the definition module informs GNU Modula-2 not to prefix the module name to exported references in the object file.

The `printf` declaration states that the first parameter semantically matches `ARRAY OF CHAR` but since the module is for the C language it will be mapped onto `char *`. The token `...` indicates a variable number of arguments (varargs) and all parameters passed here are mapped onto their C equivalents. Arrays and constant strings are passed as pointers. Lastly `[ INTEGER ]` states that the caller can ignore the function return result if desired.

The hello world program can be rewritten as:

```
MODULE hello ;

FROM libprintf IMPORT printf ;

BEGIN
   printf("hello world\n")
END hello.
```

and it can be compiled by:

```
gm2 -g -I. hello.mod -lc
```

In reality the `-lc` is redundant as libc is always included in the linking process. It is shown here to emphasize that the C library or object file containing `printf` must be present.

If a procedure function is declared using varargs then some parameter values are converted. The table below summarises the default conversions and default types used.

```
Actual Parameter       |  Default conversion  |   Type of actual
                       |                      |   value passed
================================================================
```

(continues on next page)

(continued from previous page)

```
123                     |  none               |   long long int
"hello world"           |  none               |   const char *
a: ARRAY OF CHAR        |  ADR(a)             |   char *
a: ARRAY [0..5] OF CHAR |  ADR(a)             |   char *
3.14                    |  none               |   long double
```

If you wish to pass `int` values then you should explicitly convert the constants using one of the conversion mechanisms. For example: `INTEGER(10)` or `VAL(INTEGER, 10)` or `CAST(INTEGER, 10)`.

15.16 Interface to assembly language

The interface for GNU Modula-2 to assembly language is almost identical to GNU C. The only alterations are that the keywords `asm` and `volatile` are in capitals, following the Modula-2 convention.

A simple, but highly non optimal, example is given below. Here we want to add the two `CARDINAL`s `foo` and `bar` together and return the result. The target processor is assumed to be executing the x86_64 instruction set.

```
PROCEDURE Example (foo, bar: CARDINAL) : CARDINAL ;
VAR
   myout: CARDINAL ;
BEGIN
   ASM VOLATILE ("movq %1,%%rax; addq %2,%%rax; movq %%rax,%0"
      : "=rm" (myout)            (* outputs *)
      : "rm" (foo), "rm" (bar)   (* inputs  *)
      : "rax") ;                 (* we trash *)
   RETURN( myout )
END Example ;
```

For a full description of this interface we refer the reader to the GNU C manual.

See Extended Asm - Assembler Instructions with C Expression Operands.

The same example can be written using the newer extensions of naming the operands rather than using numbered arguments.

```
PROCEDURE Example (foo, bar: CARDINAL) : CARDINAL ;
VAR
   myout: CARDINAL ;
BEGIN
   ASM VOLATILE (
    "movq %[left],%%rax; addq %[right],%%rax; movq %%rax,%[output]"
      : [output] "=rm" (myout)                  (* outputs *)
      : [left] "rm" (foo), [right] "rm" (bar)   (* inputs  *)
      : "rax") ;                                (* we trash *)
   RETURN( myout )
END Example ;
```

Both examples generate exactly the same code. It is worth noting that the specifier 'rm' indicates that the operand can be either a register or memory. Of course you must choose an instruction which can take either, but this allows the compiler to take make more efficient choices depending upon the optimization level given to the compiler.

15.17 Data type alignment

GNU Modula-2 allows you to specify alignment for types and variables. The syntax for alignment is to use the ISO pragma directives `<* bytealignment ( expression )` and `*>`. These directives can be used after type and variable declarations.

The ebnf of the alignment production is:

```
Alignment := [ ByteAlignment ] =:
ByteAlignment := '<*' AttributeExpression '*>' =:
AlignmentExpression := "(" ConstExpression ")" =:
```

The `Alignment` ebnf statement may be used during contruction of types, records, record fields, arrays, pointers and variables. Below is an example of aligning a type so that the variable `bar` is aligned on a 1024 address.

```
MODULE align ;

TYPE
   foo = INTEGER <* bytealignment(1024) *> ;

VAR
   z  : INTEGER ;
   bar: foo ;
BEGIN
END align.
```

The next example aligns a variable on a 1024 byte boundary.

```
MODULE align2 ;

VAR
   x  : CHAR ;
   z  : ARRAY [0..255] OF INTEGER <* bytealignment(1024) *> ;
BEGIN
END align2.
```

Here the example aligns a pointer on a 1024 byte boundary.

```
MODULE align4 ;

FROM SYSTEM IMPORT ADR ;
FROM libc IMPORT exit ;

VAR
```

(continues on next page)

(continued from previous page)

```
   x  : CHAR ;
   z  : POINTER TO INTEGER <* bytealignment(1024) *> ;
BEGIN
   IF ADR(z) MOD 1024=0
   THEN
      exit(0)
   ELSE
      exit(1)
   END
END align4.
```

In example `align5` record field `y` is aligned on a 1024 byte boundary.

```
MODULE align5 ;

FROM SYSTEM IMPORT ADR ;
FROM libc IMPORT exit ;

TYPE
   rec = RECORD
            x: CHAR ;
            y: CHAR <* bytealignment(1024) *> ;
         END ;
VAR
   r: rec ;
BEGIN
   IF ADR(r.y) MOD 1024=0
   THEN
      exit(0)
   ELSE
      exit(1)
   END
END align5.
```

In the example below module `align6` declares `foo` as an array of 256 `INTEGER` s. The array `foo` is aligned on a 1024 byte boundary.

```
MODULE align6 ;

FROM SYSTEM IMPORT ADR ;
FROM libc IMPORT exit ;

TYPE
   foo = ARRAY [0..255] OF INTEGER <* bytealignment(1024) *> ;

VAR
   x  : CHAR ;
   z  : foo ;
BEGIN
   IF ADR(z) MOD 1024=0
   THEN
```

(continues on next page)

(continued from previous page)

```
      exit(0)
   ELSE
      exit(1)
   END
END align6.
```

15.18 Packing data types

The pragma `<* bytealignment(0) *>` can be used to specify that the fields within a `RECORD` are to be packed. Currently this only applies to fields which are declared as subranges, ordinal types and enumerated types. Here is an example of how two subranges might be packed into a byte.

```
TYPE
   bits3c =  [0..7] ;
   bits3i = [-4..3] ;

   byte = RECORD
             <* bytealignment(0) *>
             x: bits3c ;
             <* bitsunused(2) *>
             y: bits3i ;
          END ;
```

Notice that the user has specified that in between fields `x` and `y` there are two bits unused.

Now the user wishes to create a record with byte numbers zero and one occupied and then an `INTEGER32` field which is four byte aligned. In this case byte numbers two and three will be unused. The pragma `bytealignment` can be issued at the start of the record indicating the default alignment for the whole record and this can be overridden by individual fields if necessary.

```
rec = RECORD
         <* bytealignment (1) *> ;
         a, b: byte ;
         x: INTEGER32 <* bytealignment(4) *> ;
      END ;
```

In the following example the user has specified that a record has two fields `p` and `q` but that there are three bytes unused between these fields.

```
header = RECORD
            <* bytealignment(1) *>
            p: byte ;
            <* bytesunused(3) *>
            q: byte ;
         END ;
```

The pragma `<* bytesunused(x) *>` can only be used if the current field is on a byte boundary. There is also a `SYSTEM` pseudo procedure function `TBITSIZE(T)` which returns the minimum number of bits necessary to represent type `T`.

Another example of packing record bit fields is given below:

```
MODULE align21 ;

FROM libc IMPORT exit ;

TYPE
   colour = (red, blue, green, purple, white, black) ;

   soc = PACKEDSET OF colour ;

   rec = RECORD
            <* bytealignment(0) *>
            x: soc ;
            y: [-1..1] ;
         END ;

VAR
   r: rec ;
   v: CARDINAL ;
BEGIN
   v := SIZE(r) ;
   IF SIZE(r)#1
   THEN
      exit(1)
   END ;
   r.x := soc{blue} ;
   IF r.x#soc{blue}
   THEN
      exit(2)
   END
END align21.
```

Here we see that the total size of this record is one byte and consists of a six bit set type followed by a 2 bit integer subrange.

15.19 Accessing GNU Modula-2 Built-ins

This section describes the built-in constants and functions defined in GNU Modula-2. The following compiler constants can be accessed using the `__ATTRIBUTE__ __BUILTIN__` keywords. These are not part of the Modula-2 language and they may differ depending upon the target architecture but they provide a method whereby common libraries can interface to a different underlying architecture.

The built-in constants are: `BITS_PER_UNIT`, `BITS_PER_WORD`, `BITS_PER_CHAR` and `UNITS_PER_WORD`. They are integrated into GNU Modula-2 by an extension to the `ConstFactor` rule:

```
ConstFactor := ConstQualidentOrSet | Number | ConstString |
               "(" ConstExpression ")" | "NOT" ConstFactor |
               ConstAttribute =:

ConstAttribute := "__ATTRIBUTE__" "__BUILTIN__" "(" "(" Ident ")" ")" =:
```

Here is an example taken from the ISO library `SYSTEM.def` :

```
CONST
   BITSPERLOC    = __ATTRIBUTE__ __BUILTIN__ ((BITS_PER_UNIT)) ;
   LOCSPERWORD   = __ATTRIBUTE__ __BUILTIN__ ((UNITS_PER_WORD)) ;
```

Built-in functions are transparent to the end user. All built-in functions are declared in `DEFINITION MODULE` s and are imported as and when required. Built-in functions are declared in definition modules by using the `__BUILTIN__` keyword. Here is a section of the ISO library `LongMath.def` which demonstrates this feature.

```
PROCEDURE __BUILTIN__ sqrt (x: LONGREAL): LONGREAL;
  (* Returns the square root of x *)
```

This indicates that the function `sqrt` will be implemented using the gcc built-in maths library. If gcc cannot utilise the built-in function (for example if the programmer requested the address of `sqrt`) then code is generated to call the alternative function implemented in the `IMPLEMENTATION MODULE`.

Sometimes a function exported from the `DEFINITION MODULE` will have a different name from the built-in function within gcc. In such cases the mapping between the GNU Modula-2 function name and the gcc name is expressed using the keywords `__ATTRIBUTE__ __BUILTIN__ ((Ident))`. For example the function `sqrt` in `LongMath.def` maps onto the gcc built-in function `sqrtl` and this is expressed as:

```
PROCEDURE __ATTRIBUTE__ __BUILTIN__ ((sqrtl)) sqrt
                                    (x: LONGREAL) : LONGREAL;
  (* Returns the positive square root of x *)
```

The following module `Builtins.def` enumerates the list of built-in functions which can be accessed in GNU Modula-2. It also serves to define the parameter and return value for each function:

```
DEFINITION MODULE Builtins ;

FROM SYSTEM IMPORT ADDRESS ;

(* floating point intrinsic procedure functions *)

```

Although this module exists and will result in the generation of in-line code if optimization flags are passed to GNU Modula-2, users are advised to utilize the same functions from more generic libraries. The built-in mechanism will be applied to these generic libraries where appropriate. Note for the mathematical routines to be in-lined you need to specify the `-ffast-math -O` options.

(*
   all the functions below are declared internally to gm2
   ======================================================

ADR
PROCEDURE ADR (VAR v: <anytype>): ADDRESS;
  (* Returns the address of variable v. *)

SIZE
```

(continues on next page)

(continued from previous page)

```
PROCEDURE SIZE (v: <type>) : ZType;
  (* Returns the number of BYTES used to store a v of
     any specified <type>.  Only available if -fpim2 is used.
  *)

TSIZE
PROCEDURE TSIZE (<type>) : CARDINAL;
  (* Returns the number of BYTES used to store a value of the
     specified <type>.
  *)

ROTATE
PROCEDURE ROTATE (val: <a set type>;
                  num: INTEGER): <type of first parameter>;
  (* Returns a bit sequence obtained from val by rotating up/right
     or down/right by the absolute value of num.  The direction is
     down/right if the sign of num is negative, otherwise the direction
     is up/left.
  *)

SHIFT
PROCEDURE SHIFT (val: <a set type>;
                 num: INTEGER): <type of first parameter>;
  (* Returns a bit sequence obtained from val by shifting up/left
     or down/right by the absolute value of num, introducing
     zeros as necessary.  The direction is down/right if the sign of
     num is negative, otherwise the direction is up/left.
  *)

THROW
PROCEDURE THROW (i: INTEGER) ;
  (*
     THROW is a GNU extension and was not part of the PIM or ISO
     standards.  It throws an exception which will be caught by the
     EXCEPT block (assuming it exists).  This is a compiler builtin
     function which interfaces to the GCC exception handling runtime
     system.
     GCC uses the term throw, hence the naming distinction between
     the GCC builtin and the Modula-2 runtime library procedure Raise.
     The later library procedure Raise will call SYSTEM.THROW after
     performing various housekeeping activities.
  *)

TBITSIZE
PROCEDURE TBITSIZE (<type>) : CARDINAL ;
  (* Returns the minimum number of bits necessary to represent
     <type>.  This procedure function is only useful for determining
     the number of bits used for any type field within a packed RECORD.
     It is not particularly useful elsewhere since <type> might be
     optimized for speed, for example a BOOLEAN could occupy a WORD.
  *)
```

(continues on next page)

(continued from previous page)

```
*)

(* The following procedures are invoked by GNU Modula-2 to
   shift non word sized set types. They are not strictly part
   of the core PIM Modula-2, however they are used by
   GNU Modula-2 to implement the SHIFT procedure defined above,
   which are in turn used by the Logitech compatible libraries.

   Users will access these procedures by using the procedure
   SHIFT above and GNU Modula-2 will map SHIFT onto one of
   the following procedures.
*)

(*
   ShiftVal - is a runtime procedure whose job is to implement
              the SHIFT procedure of ISO SYSTEM. GNU Modula-2 will
              inline a SHIFT of a single WORD sized set and will only
              call this routine for larger sets.
*)

ShiftVal

                 GNU Modula-2 depending whether amount is known at
                 compile time.
*)

RotateRight
PROCEDURE RotateRight (VAR s, d: ARRAY OF BITSET;
                       SetSizeInBits: CARDINAL;
                       RotateCount: CARDINAL) ;

END SYSTEM.
```

The different dialects of Modula-2 PIM-[234] and ISO Modula-2 declare the function `SIZE` in different places. PIM-[34] and ISO Modula-2 declare `SIZE` as a pervasive function (declared in the base module). PIM-2 defined `SIZE` in the `SYSTEM` module (as shown above).

GNU Modula-2 allows users to specify the dialect of Modula-2 by using the `-fiso` and `-fpim2` command line switches.

The data types `CSIZE_T` and `CSSIZE_T` are also exported from the `SYSTEM` module. The type `CSIZE_T` is unsigned and is mapped onto the target C data type `size_t` whereas the type `CSSIZE_T` is mapped onto the signed C data type `ssize_t`.

It is anticipated that these should only be used to provide cross platform definition modules for C libraries.

There are also a variety of fixed sized `INTEGER` and `CARDINAL` types. The variety of the fixed sized

types will depend upon the target architecture.

15.21 The ISO system module

```
DEFINITION MODULE SYSTEM;

  (* Gives access to system programming facilities that are probably
     non portable. *)

  (* The constants and types define underlying properties of storage *)

TYPE
BYTE (type)
  BYTE = ARRAY [0 .. LOCSPERBYTE-1] OF LOC;

ADDADR
PROCEDURE ADDADR (addr: ADDRESS; offset: CARDINAL): ADDRESS;
  (* Returns address given by (addr + offset), or may raise
     an exception if this address is not valid.
  *)

SUBADR
PROCEDURE SUBADR (addr: ADDRESS; offset: CARDINAL): ADDRESS;
  (* Returns address given by (addr - offset), or may raise an
     exception if this address is not valid.
  *)

DIFADR
PROCEDURE DIFADR (addr1, addr2: ADDRESS): INTEGER;
  (* Returns the difference between addresses (addr1 - addr2),
     or may raise an exception if the arguments are invalid
     or address space is non-contiguous.
  *)

MAKEADR
PROCEDURE MAKEADR (high: <some type>; ...): ADDRESS;
  (* Returns an address constructed from a list of values whose
     types are implementation-defined, or may raise an
     exception if this address is not valid.

     In GNU Modula-2, MAKEADR can take any number of arguments
     which are mapped onto the type ADDRESS. The first parameter
     maps onto the high address bits and subsequent parameters map
     onto lower address bits. For example:

     a := MAKEADR(BYTE(0FEH), BYTE(0DCH), BYTE(0BAH), BYTE(098H),
                  BYTE(076H), BYTE(054H), BYTE(032H), BYTE(010H)) ;

     then the value of, a, on a 64 bit machine is: 0FEDCBA9876543210H

     The parameters do not have to be the same type, but constants
     _must_ be typed.
  *)

ADR
PROCEDURE ADR (VAR v: <anytype>): ADDRESS;
  (* Returns the address of variable v. *)
```

(continues on next page)

(continued from previous page)

```
ROTATE
PROCEDURE ROTATE (val: <a packedset type>;
                  num: INTEGER): <type of first parameter>;
  (* Returns a bit sequence obtained from val by rotating up/right
     or down/right by the absolute value of num.  The direction is
     down/right if the sign of num is negative, otherwise the direction
     is up/left.
  *)

SHIFT
PROCEDURE SHIFT (val: <a packedset type>;
                 num: INTEGER): <type of first parameter>;
  (* Returns a bit sequence obtained from val by shifting up/left
     or down/right by the absolute value of num, introducing
     zeros as necessary.  The direction is down/right if the sign of
     num is negative, otherwise the direction is up/left.
  *)

CAST
PROCEDURE CAST (<targettype>; val: <anytype>): <targettype>;
  (* CAST is a type transfer function.  Given the expression
     denoted by val, it returns a value of the type <targettype>.
     An invalid value for the target value or a
     physical address alignment problem may raise an exception.
  *)

TSIZE
PROCEDURE TSIZE (<type>; ... ): CARDINAL;
  (* Returns the number of LOCS used to store a value of the
     specified <type>.   The extra parameters, if present,
     are used to distinguish variants in a variant record.
  *)

THROW
PROCEDURE THROW (i: INTEGER) ;
  (*
     THROW is a GNU extension and was not part of the PIM or ISO
     standards.  It throws an exception which will be caught by the
     EXCEPT block (assuming it exists).  This is a compiler builtin
     function which interfaces to the GCC exception handling runtime
     system.
     GCC uses the term throw, hence the naming distinction between
     the GCC builtin and the Modula-2 runtime library procedure Raise.
     The later library procedure Raise will call SYSTEM.THROW after
     performing various housekeeping activities.
  *)

TBITSIZE
PROCEDURE TBITSIZE (<type>) : CARDINAL ;
  (* Returns the minimum number of bits necessary to represent
     <type>.  This procedure function is only useful for determining
```

(continues on next page)

(continued from previous page)

```
     the number of bits used for any type field within a packed RECORD.
     It is not particularly useful elsewhere since <type> might be
     optimized for speed, for example a BOOLEAN could occupy a WORD.
  *)
*)

(* The following procedures are invoked by GNU Modula-2 to
   shift non word set types. They are not part of ISO Modula-2
   but are used by GNU Modula-2 to implement the SHIFT procedure
   defined above. *)

(*
   ShiftVal - is a runtime procedure whose job is to implement
              the SHIFT procedure of ISO SYSTEM. GNU Modula-2 will
              inline a SHIFT of a single WORD sized set and will only
              call this routine for larger sets.
*)

ShiftVal
PROCEDURE ShiftVal (VAR s, d: ARRAY OF BITSET;
                    SetSizeInBits: CARDINAL;
                    ShiftCount: INTEGER) ;

(*
   ShiftLeft - performs the shift left for a multi word set.
               This procedure might be called by the back end of
               GNU Modula-2 depending whether amount is known at
               compile time.
*)

ShiftLeft
PROCEDURE ShiftLeft (VAR s, d: ARRAY OF BITSET;
                     SetSizeInBits: CARDINAL;
                     ShiftCount: CARDINAL) ;

(*
   ShiftRight - performs the shift left for a multi word set.
                This procedure might be called by the back end of
                GNU Modula-2 depending whether amount is known at
                compile time.
*)

ShiftRight
PROCEDURE ShiftRight (VAR s, d: ARRAY OF BITSET;
                      SetSizeInBits: CARDINAL;
                      ShiftCount: CARDINAL) ;

(*
   RotateVal - is a runtime procedure whose job is to implement
               the ROTATE procedure of ISO SYSTEM. GNU Modula-2 will
               inline a ROTATE of a single WORD (or less)
```

(continues on next page)

(continued from previous page)

```
               sized set and will only call this routine for larger
               sets.
*)

RotateVal
PROCEDURE RotateVal (VAR s, d: ARRAY OF BITSET;
                     SetSizeInBits: CARDINAL;
                     RotateCount: INTEGER) ;

(*
   RotateLeft - performs the rotate left for a multi word set.
                This procedure might be called by the back end of
                GNU Modula-2 depending whether amount is known at
                compile time.
*)

RotateLeft
PROCEDURE RotateLeft (VAR s, d: ARRAY OF BITSET;
                      SetSizeInBits: CARDINAL;
                      RotateCount: CARDINAL) ;

(*
   RotateRight - performs the rotate right for a multi word set.
                 This procedure might be called by the back end of
                 GNU Modula-2 depending whether amount is known at
                 compile time.
*)

RotateRight
PROCEDURE RotateRight (VAR s, d: ARRAY OF BITSET;
                       SetSizeInBits: CARDINAL;
                       RotateCount: CARDINAL) ;

END SYSTEM.
```

The data types `CSIZE_T` and `CSSIZE_T` are also exported from the `SYSTEM` module. The type `CSIZE_T` is unsigned and is mapped onto the target C data type `size_t` whereas the type `CSSIZE_T` is mapped onto the signed C data type `ssize_t`.

It is anticipated that these should only be used to provide cross platform definition modules for C libraries.

There are also a variety of fixed sized `INTEGER` and `CARDINAL` types. The variety of the fixed sized types will depend upon the target architecture.

This document contains the user and design issues relevant to the Modula-2 front end to gcc. Throughout this document the GNU Modula-2 front end is often referred to as `gm2-1.9.5` or `gm2` for short. This corresponds to GCC version 13.0.0 and GNU Modula-2 version 1.9.5.

CHAPTER

SIXTEEN

LICENCE OF GNU MODULA-2

GNU Modula-2 is free software, the compiler is held under the GPL v3 http://www.gnu.org/licenses/gpl.txt, its libraries (pim, iso and Logitech compatible) are under the GPL v3 with the GCC runtime library exception clause.

Under Section 7 of GPL version 3, you are granted additional permissions described in the GCC Runtime Library Exception, version 3.1, as published by the Free Software Foundation.

You should have received a copy of the GNU General Public License and a copy of the GCC Runtime Library Exception along with this program; see the files COPYING3 and COPYING.RUNTIME respectively. If not, see <http://www.gnu.org/licenses/>.

More information on how these licences work is available http://www.gnu.org/licenses/licenses.html on the GNU web site.

CHAPTER

SEVENTEEN

EBNF OF GNU MODULA-2

This chapter contains the EBNF of GNU Modula-2. This grammer currently supports both PIM and ISO dialects. The rules here are automatically extracted from the grammer files in GNU Modula-2 and serve to document the syntax of the extensions described earlier and how they fit in with the base language.

Note that the first six productions are built into the lexical analysis phase.

CHAPTER

EIGHTEEN

PIM AND ISO LIBRARY DEFINITIONS

This chapter contains M2F, PIM and ISO libraries.

18.1 Base libraries

These are the base libraries for the GNU Modula-2 compiler. These modules originally came from the M2F compiler and have been cleaned up and extended. They provide a basic interface to the underlying operating system via libc. They also include a number of libraries to allow access to compiler built-ins. Perhaps the largest difference to PIM and ISO libraries is the `DynamicString` module which declares the type `String`. The heavy use of this opaque data type results in a number of equivalent modules that can either handle `ARRAY OF CHAR` or `String`.

These modules have been extensively tested and are used throughout building the GNU Modula-2 compiler.

18.1.1 gm2-libs/ASCII

```
DEFINITION MODULE ASCII ;

EXPORT QUALIFIED
     nul, soh, stx, etx, eot, enq, ack, bel,

*)

InitLongOptions
PROCEDURE InitLongOptions () : LongOptions ;

(*
   AddLongOption - appends long option {name, has_arg, flag, val} to the
                   array of options and new long options array is
```

(continues on next page)

(continued from previous page)

```
                  returned.
                  The old array, lo, should no longer be used.

   (from man 3 getopt)
       The meanings of the different fields are:

       name   is the name of the long option.

       has_arg
              is: no_argument (or 0) if the option does not take an
              argument; required_argument (or  1) if the option
              requires an argument; or optional_argument (or 2) if
              the option takes an optional argument.

       flag   specifies how results are returned for a long option.
              If flag is NULL, then getopt_long() returns val.
              (For example, the calling program may set val to the
              equivalent short option character).  Otherwise,
              getopt_long() returns 0, and flag points to a
              variable which is set to val if the option is found,
              but left unchanged if the option is not found.

       val    is the value to return, or to load into the variable
              pointed to by flag.

       The last element of the array has to be filled with zeros.
*)

  (* Returns a bit sequence obtained from val by shifting up/left
     or down/right by the absolute value of num, introducing
     zeros as necessary.  The direction is down/right if the sign of
     num is negative, otherwise the direction is up/left.
  *)

THROW
PROCEDURE THROW (i: INTEGER) ;
  (*
     THROW is a GNU extension and was not part of the PIM or ISO
     standards.  It throws an exception which will be caught by the
     EXCEPT block (assuming it exists).  This is a compiler builtin
     function which interfaces to the GCC exception handling runtime
     system.
     GCC uses the term throw, hence the naming distinction between
     the GCC builtin and the Modula-2 runtime library procedure Raise.
     The later library procedure Raise will call SYSTEM.THROW after
     performing various housekeeping activities.
  *)

TBITSIZE
PROCEDURE TBITSIZE (<type>) : CARDINAL ;
  (* Returns the minimum number of bits necessary to represent
     <type>.  This procedure function is only useful for determining
     the number of bits used for any type field within a packed RECORD.
     It is not particularly useful elsewhere since <type> might be
     optimized for speed, for example a BOOLEAN could occupy a WORD.
  *)
*)

(* The following procedures are invoked by GNU Modula-2 to
   shift non word sized set types. They are not strictly part
   of the core PIM Modula-2, however they are used by
   GNU Modula-2 to implement the SHIFT procedure defined above,
   which are in turn used by the Logitech compatible libraries.

   Users will access these procedures by using the procedure
   SHIFT above and GNU Modula-2 will map SHIFT onto one of
   the following procedures.
*)

StringToLongreal
PROCEDURE StringToLongreal (s: String; VAR found: BOOLEAN) : LONGREAL ;

(*
   LongrealToString - converts a LONGREAL number, Real, which has,
                      TotalWidth, and FractionWidth into a string.

                      So for example:

                      LongrealToString(1.0, 4, 2)  -> '1.00'
                      LongrealToString(12.3, 5, 2) -> '12.30'
                      LongrealToString(12.3, 6, 2) -> ' 12.30'
                      LongrealToString(12.3, 6, 3) -> '12.300'

                      if total width is too small then the fraction
                      becomes truncated.

                      LongrealToString(12.3, 5, 3) -> '12.30'

                      If TotalWidth is 0 then the function
```

(*
   getopt - the getopt() function parses the command-line arguments.
            Its arguments argc and argv are the argument count and array as
            passed to the main() function on program invocation.  An element of
            argv that starts with '-' (and is not exactly "-" or "--") is an
            option element.  The characters of this element (aside from the
            initial '-') are option characters.  If getopt() is called
            repeatedly, it returns successively each of the option characters
            from each of the option elements.

18.2 PIM coroutine support

This directory contains a PIM `SYSTEM` containing the `PROCESS` primitives built on top of GNU Pthreads.

The justification for this approach is that it provides a `SYSTEM` compatible with Programming in Modula-2 [234] and the Logitech 3.0 compiler. It also allows higher level executives to be ported onto GM2 with little effort. The disadvantage with this approach is that `IOTRANSFER` is not preemptive. `IOTRANSFER` will only context switch when a call to `LISTEN` is made or a call to `SYSTEM.TurnInterrupts` is made.

In practice this limitation can be tolerated as long as processes perform IO at some point (or wait for a timer interrupt) or call `SYSTEM.TurnInterrupts`. But nevertheless a `LOOP END` will starve all other processes. However the great advantage is that GNU Modula-2 can offer users the ability to use `IOTRANSFER`, `TRANSFER`, `NEWPROCESS` in user space, on a multi-user operating system and across a range of platforms.

The GNU Modula-2 `SYSTEM` works by utilizing the user context switching mechanism provided by GNU Pthreads. `NEWPROCESS` creates a new context, `TRANSFER` switches contexts. `IOTRANSFER` is more complex. There is a support module `SysVec` which provides pseudo interrupt vectors. These can be created from input/output file descriptors or timer events `timeval`. This vector is then passed to `IOTRANSFER` which keeps track of which file descriptors and timevals are active. When a call to `TurnInterrupts` or `LISTEN` is made the sub system calls `pth_select` and tests for any ready file descriptor or timeout. A ready file descriptor or timeout will ultimately cause the backwards `TRANSFER` inside `IOTRANSFER` to take effect.

See the `gm2/examples/executive` directory for an executive and timerhandler module which provide higher level process creation, synchronisation and interrupt handling routines. These libraries have been tested with the examples shown in `gm2/examples/executive` and `gm2/gm2-libs-coroutines`.

Users of these libraries and the libraries in `gm2/examples/executive` must link their application against the GNU Pthread library (typically by using `-lpth`).

(*
   TRANSFER - save the current volatile environment into, p1.
              Restore the volatile environment from, p2.
*)

TRANSFER
PROCEDURE TRANSFER (VAR p1: PROCESS; p2: PROCESS) ;

(*
   NEWPROCESS - p is a parameterless procedure, a, is the origin of
                the workspace used for the process stack and containing
                the volatile environment of the process.  StackSize, is
                the maximum size of the stack in bytes which can be used
                by this process.  new, is the new process.
*)

NEWPROCESS
PROCEDURE NEWPROCESS (p: PROC; a: ADDRESS; StackSize: CARDINAL; VAR new: PROCESS) ;

(*
   IOTRANSFER - saves the current volatile environment into, First,
                and restores volatile environment, Second.
                When an interrupt, InterruptNo, is encountered then
                the reverse takes place. (The then current volatile
                environment is shelved onto Second and First is resumed).

                NOTE: that upon interrupt the Second might not be the
                      same process as that before the original call to
                      IOTRANSFER.
*)

IOTRANSFER
PROCEDURE IOTRANSFER (VAR First, Second: PROCESS; InterruptNo: CARDINAL) ;

(*
   LISTEN - briefly listen for any interrupts.
*)
```

(continues on next page)

(continued from previous page)

```
LISTEN
PROCEDURE LISTEN ;

(*
   ListenLoop - should be called instead of users writing:

                LOOP
                   LISTEN
                END

                It performs the same function but yields
                control back to the underlying operating system
                via a call to pth_select.
                It also checks for deadlock.
                This function returns when an interrupt occurs ie
                a file descriptor becomes ready or a time event expires.
                See the module RTint.
*)

ListenLoop
PROCEDURE ListenLoop ;

(*
   TurnInterrupts - switches processor interrupts to the protection
                    level, to.  It returns the old value.
*)

TurnInterrupts
PROCEDURE TurnInterrupts (to: PROTECTION) : PROTECTION ;

(*
   all the functions below are declared internally to gm2
   ======================================================

ADR
PROCEDURE ADR (VAR v: <anytype>): ADDRESS;
  (* Returns the address of variable v. *)

SIZE
PROCEDURE SIZE (v: <type>) : ZType;
  (* Returns the number of BYTES used to store a v of
     any specified <type>.  Only available if -fpim2 is used.
  *)

TSIZE
PROCEDURE TSIZE (<type>) : CARDINAL;
  (* Returns the number of BYTES used to store a value of the
     specified <type>.
  *)

ROTATE
```

(continues on next page)

(continued from previous page)

```
PROCEDURE ROTATE (val: <a set type>;
                  num: INTEGER): <type of first parameter>;
  (* Returns a bit sequence obtained from val by rotating up or down
     (left or right) by the absolute value of num.  The direction is
     down if the sign of num is negative, otherwise the direction is up.
  *)

SHIFT
PROCEDURE SHIFT (val: <a set type>;
                 num: INTEGER): <type of first parameter>;
  (* Returns a bit sequence obtained from val by shifting up or down
     (left or right) by the absolute value of num, introducing
     zeros as necessary.  The direction is down if the sign of
     num is negative, otherwise the direction is up.
  *)

THROW
PROCEDURE THROW (i: INTEGER) ;
  (*
     THROW is a GNU extension and was not part of the PIM or ISO
     standards.  It throws an exception which will be caught by the EXCEPT
     block (assuming it exists).  This is a compiler builtin function which
     interfaces to the GCC exception handling runtime system.
     GCC uses the term throw, hence the naming distinction between
     the GCC builtin and the Modula-2 runtime library procedure Raise.
     The later library procedure Raise will call SYSTEM.THROW after
     performing various housekeeping activities.
  *)

TBITSIZE
PROCEDURE TBITSIZE (<type>) : CARDINAL ;
  (* Returns the minimum number of bits necessary to represent
     <type>.  This procedure function is only useful for determining
     the number of bits used for any type field within a packed RECORD.
     It is not particularly useful elsewhere since <type> might be
     optimized for speed, for example a BOOLEAN could occupy a WORD.
  *)
*)

(* The following procedures are invoked by GNU Modula-2 to
   shift non word sized set types. They are not strictly part
   of the core PIM Modula-2, however they are used by
   GNU Modula-2 to implement the SHIFT procedure defined above,
   which are in turn used by the Logitech compatible libraries.

   Users will access these procedures by using the procedure
   SHIFT above and GNU Modula-2 will map SHIFT onto one of
   the following procedures.
*)

(*
```

(continues on next page)

(continued from previous page)

```
   ShiftVal - is a runtime procedure whose job is to implement
              the SHIFT procedure of ISO SYSTEM. GNU Modula-2 will
              inline a SHIFT of a single WORD sized set and will only
              call this routine for larger sets.
*)

ShiftVal

ADDADR
PROCEDURE ADDADR (addr: ADDRESS; offset: CARDINAL): ADDRESS;
  (* Returns address given by (addr + offset), or may raise
     an exception if this address is not valid.
  *)

SUBADR
PROCEDURE SUBADR (addr: ADDRESS; offset: CARDINAL): ADDRESS;
  (* Returns address given by (addr - offset), or may raise an
     exception if this address is not valid.
  *)

DIFADR
PROCEDURE DIFADR (addr1, addr2: ADDRESS): INTEGER;
  (* Returns the difference between addresses (addr1 - addr2),
     or may raise an exception if the arguments are invalid
     or address space is non-contiguous.
  *)

MAKEADR
PROCEDURE MAKEADR (high: <some type>; ...): ADDRESS;
  (* Returns an address constructed from a list of values whose
     types are implementation-defined, or may raise an
     exception if this address is not valid.
```

(continues on next page)

(continued from previous page)

```
    In GNU Modula-2, MAKEADR can take any number of arguments
    which are mapped onto the type ADDRESS. The first parameter
    maps onto the high address bits and subsequent parameters map
    onto lower address bits. For example:

    a := MAKEADR(BYTE(0FEH), BYTE(0DCH), BYTE(0BAH), BYTE(098H),
                 BYTE(076H), BYTE(054H), BYTE(032H), BYTE(010H)) ;

    then the value of, a, on a 64 bit machine is: 0FEDCBA9876543210H

    The parameters do not have to be the same type, but constants
    _must_ be typed.
  *)

ADR
PROCEDURE ADR (VAR v: <anytype>): ADDRESS;
  (* Returns the address of variable v. *)

ROTATE
PROCEDURE ROTATE (val: <a packedset type>;
                  num: INTEGER): <type of first parameter>;
  (* Returns a bit sequence obtained from val by rotating up/right
     or down/right by the absolute value of num.  The direction is
     down/right if the sign of num is negative, otherwise the direction
     is up/left.
  *)

SHIFT
PROCEDURE SHIFT (val: <a packedset type>;
                 num: INTEGER): <type of first parameter>;
  (* Returns a bit sequence obtained from val by shifting up/left
     or down/right by the absolute value of num, introducing
     zeros as necessary.  The direction is down/right if the sign of
     num is negative, otherwise the direction is up/left.
  *)

CAST
PROCEDURE CAST (<targettype>; val: <anytype>): <targettype>;
  (* CAST is a type transfer function.  Given the expression
     denoted by val, it returns a value of the type <targettype>.
     An invalid value for the target value or a
     physical address alignment problem may raise an exception.
  *)

TSIZE
PROCEDURE TSIZE (<type>; ... ): CARDINAL;
  (* Returns the number of LOCS used to store a value of the
     specified <type>.   The extra parameters, if present,
     are used to distinguish variants in a variant record.
  *)
```

(continues on next page)

(continued from previous page)

```
THROW
PROCEDURE THROW (i: INTEGER) ;
  (*
     THROW is a GNU extension and was not part of the PIM or ISO
     standards.  It throws an exception which will be caught by the
     EXCEPT block (assuming it exists).  This is a compiler builtin
     function which interfaces to the GCC exception handling runtime
     system.
     GCC uses the term throw, hence the naming distinction between
     the GCC builtin and the Modula-2 runtime library procedure Raise.
     The later library procedure Raise will call SYSTEM.THROW after
     performing various housekeeping activities.
  *)

TBITSIZE
PROCEDURE TBITSIZE (<type>) : CARDINAL ;
  (* Returns the minimum number of bits necessary to represent
     <type>.  This procedure function is only useful for determining
     the number of bits used for any type field within a packed RECORD.
     It is not particularly useful elsewhere since <type> might be
     optimized for speed, for example a BOOLEAN could occupy a WORD.
  *)
*)

(* The following procedures are invoked by GNU Modula-2 to
   shift non word set types. They are not part of ISO Modula-2
   but are used by GNU Modula-2 to implement the SHIFT procedure
   defined above. *)

(*
   ShiftVal - is a runtime procedure whose job is to implement
              the SHIFT procedure of ISO SYSTEM. GNU Modula-2 will
              inline a SHIFT of a single WORD sized set and will only
              call this routine for larger sets.
*)

18.4 PIM and Logitech 3.0 Compatible

These modules are provided to enable legacy Modula-2 applications to build with GNU Modula-2. It is advised that these module should not be used for new projects, maybe the ISO libraries or the native compiler PIM libraries (FIO) should be used instead.

Here is an outline of the module layering:

```
InOut  RealInOut  LongIO CardinalIO
    \     |       |      /
          Terminal
----------------------------------
             |
          Termbase
          /      \
    Keyboard      Display
```

Above the line are user level PIM [234] and Logitech 3.0 compatible modules. Below the line Logitech 3.0 advised that these modules should be considered part of the runtime system. The libraries do not provide all the features found in the Logitech libraries as a number of these features were MS-DOS related. Essentially the basic input/output, file system, string manipulation and conversion routines are provided. Access to DOSCALL, graphics, time and date are not as these were constrained by the limitations of MS-DOS.

The following libraries are contained within the base GNU Modula-2 libraries but are also Logitech-3.0 compatible: ASCII, Storage and MathLib0.

18.4.1 gm2-libs-pim/BitBlockOps

```
DEFINITION MODULE BitBlockOps ;

FROM SYSTEM IMPORT ADDRESS ;

(*
   BlockAnd - performs a bitwise AND on blocks
              [dest..dest+size-1] := [dest..dest+size-1] AND
                                     [src..src+size-1]
*)
```

(continues on next page)

(continued from previous page)

```
BlockAnd
PROCEDURE BlockAnd (dest, src: ADDRESS; size: CARDINAL) ;

(*
   BlockOr - performs a bitwise OR on blocks
             [dest..dest+size-1] := [dest..dest+size-1] OR
                                    [src..src+size-1]
*)

BlockOr
PROCEDURE BlockOr (dest, src: ADDRESS; size: CARDINAL) ;

(*
   BlockXor - performs a bitwise XOR on blocks
              [dest..dest+size-1] := [dest..dest+size-1] XOR
                                     [src..src+size-1]
*)

BlockXor
PROCEDURE BlockXor (dest, src: ADDRESS; size: CARDINAL) ;

(*
   BlockNot - performs a bitsize NOT on the block as defined
              by:  [dest..dest+size-1]
*)

BlockNot
PROCEDURE BlockNot (dest: ADDRESS; size: CARDINAL) ;

(*
   BlockShr - performs a block shift right of, count, bits.
              Where the block is defined as:
              [dest..dest+size-1].
              The block is considered to be an ARRAY OF BYTEs
              which is shifted, bit at a time over each byte in
              turn.  The left most byte is considered the byte
              located at the lowest address.
              If you require an endianness SHIFT use
              the SYSTEM.SHIFT procedure and declare the
              block as a POINTER TO set type.
*)

(*
   SetNoOfExponentDigits - sets the number of exponent digits to be
                           used during future calls of LongRealToString
                           and RealToString providing that the width
                           is sufficient.
                           If this value is set to 0 (the default) then
                           the number digits used is the minimum necessary.
*)

SetNoOfExponentDigits
PROCEDURE SetNoOfExponentDigits (places: CARDINAL) ;

(*
   RealToString - converts a real, r, into a right justified string, str.
                  The number of digits to the right of the decimal point
                  is given in, digits.  The value, width, represents the
                  maximum number of characters to be used in the string,
                  str.

                  If digits is negative then exponent notation is used
                  whereas if digits is positive then fixed point notation
                  is used.

                  If, r, is less than 0.0 then a '-' preceeds the value,
                  str.  However, if, r, is >= 0.0 a '+' is not added.

                  If the conversion of, r, to a string requires more
                  than, width, characters then the string, str, is set
                  to a nul string and, ok is assigned FALSE.

                  For fixed point notation the minimum width required is
                  ABS(width)+8

                  For exponent notation the minimum width required is
                  ABS(digits)+2+log10(magnitude).

                  if r is a NaN then the string 'nan' is returned formatted and
                  ok will be FALSE.
*)

RealToString
PROCEDURE RealToString (r: REAL; digits, width: INTEGER;
                        VAR str: ARRAY OF CHAR; VAR ok: BOOLEAN) ;
```

(continues on next page)

(continued from previous page)

```
(*
   LongRealToString - converts a real, r, into a right justified string, str.
                      The number of digits to the right of the decimal point
                      is given in, digits. The value, width, represents the
                      maximum number of characters to be used in the string,
                      str.

                      If digits is negative then exponent notation is used
                      whereas if digits is positive then fixed point notation
                      is used.

                      If, r, is less than 0.0 then a '-' preceeds the value,
                      str. However, if, r, is >= 0.0 a '+' is not added.
